Abstract

Four-dimensional supersymmetric SU(N) Yang-Mills theory on a sphere has highly charged baryon-like states built from anti-symmetric combinations of the adjoint scalars. We show that these states, which are equivalently described as holes in a free fermi sea of a reduced matrix model, are D-branes. Their excitations are stringlike and effectively realize Dirichlet and Neumann boundary conditions in various directions. The low energy brane dynamics should realize an emergent gauge theory that is local on a new space. We show that the Gauss' Law associated to this emergent gauge symmetry appears from combinatorial identities relating the stringy excitations. Although these excitations are not BPS, they can be near-BPS and we can hope to study them in perturbation theory. Accordingly, we show that the Chan-Paton factors expected for strings propagating on multiple branes arise dynamically, allowing the emergent gauge symmetry to be non-Abelian.

1 Introduction

It is known that Yang-Mills theory with many colours has a relation to a theory of closed strings [1]. Indeed, the AdS/CFT correspondence showed that certain Yang-Mills theories are exactly equivalent to fundamental string theories in AdS backgrounds [2]. Since such closed string theories also contain D-branes and hence open string dynamics, one expects that Yang-Mills theories contains sectors which display open string dynamics and thus the dynamical emergence of new non-Abelian gauge symmetries. The purpose of this paper is to study how this happens in the $\mathcal{N} = 4$ SU(N) Yang-Mills theory on a sphere that is dual to IIB string theory in global $\mathrm{AdS}_5 \times S^5$.

Our computational techniques will require extrapolation from weak to strong coupling, and thus we are particularly interested in states that do not receive large quantum corrections. For this reason it is convenient to start with 1/2-BPS D-brane states of $\mathcal{N} = 4$ Yang-Mills theory, which we describe in Sec. 2. The dual description of these states in string theory on $\mathrm{AdS}_5 \times S^5$ is as "giant gravitons" [3, 4, 5], or spherical branes, that expand out into the AdS_5 or into the S^5. The relevant Yang-Mills operators were described in [6, 7]. Extensive study of these states has culminated with the understanding that there is a reduced matrix model which describes them. The matrix model is studied most efficiently in terms of the free fermionic description of the eigenvalues [8], and it turns out that the two types of giant gravitons can be understood either as the fermions themselves, or as hole wavefunctions. This insight has been further confirmed by the construction of all half BPS supergravity solutions with asymptotic $AdS_5 \times S^5$ boundary conditions [9] (see also [10] for some earlier work).

One class of these states – corresponding to spherical D-branes that expand into AdS_5 – is described in the semiclassical limit as the a time-dependent analog of a Coulomb branch for the field theory on a sphere [4]. We explain this in Sec. 3 and show therefore that the gauge dynamics of D-branes in spacetime is simply embedded in the residual gauge symmetry that survives the (time-dependent) Higgs effect in the field theory. In Sec. 4 we describe the Yang-Mills operators dual to spherical branes that expand into S^5 and establish that the excitations around states created by these operators are open string-like and realize the Dirichlet and Neumann boundary conditions expected for a D-brane. This completes the evidence accumulated in [11, 12, 13] for the branelike nature of such states. In the M-theory plane wave it has been argued that tiny giant gravitons are the partons that give rise to the matrix degrees of freedom of the plane wave matrix model [14]. One can extrapolate this idea further and say that giant gravitons generate the global $AdS_5 \times S^5$ geometry [9], where we have replaced them by the flux background they generate.

In Sec. 5 we propose operators describing the open string excitations of multi-brane states. They are not naive products of single brane operators, but are strongly constrained by the required symmetries. The low energy dynamics of such strings should realize a new gauge theory on the brane worldvolume. The simplest manifestation of a gauge theory on a compact space is that Gauss' Law only allows excitations within vanishing total charge. In our proposal, Gauss' law emerges from combinatorial identities due to which states that are gauge-invariant in the original Yang-Mills theory, but charged in the emergent theory on the D-branes, are impossible to construct.[1] While such open string excitations on D-branes are not BPS, they can be near-BPS and hence one can hope to study their dynamics in perturbation at weak coupling and then extrapolate to strong coupling.

Carrying out such studies in Sec. 6, we show that the Chan-Paton factors that appear in open-string loop diagrams in the presence of multiple branes emerge dynamically from Yang-Mills calculations. In particular, we find that as two D-branes separate, the associated Chan-Paton factor interpolates between 2 and 1. The section concludes with some attempts to study the interactions of the open strings that have emerged from Yang-Mills theory.

2 $U(N)$ Matrix models and 1/2-BPS states

We are interested in the 1/2-BPS states of $\mathcal{N} = 4$ Yang-Mills theory that are dual to compact D-branes (giant gravitons) in $\mathrm{AdS}_5 \times S^5$. To construct the relevant operators it is helpful to recall some elementary facts about the 1/2-BPS operators.

Recall that $\mathcal{N} = 4$ Yang-Mills theory has three chiral superfields. The 1/2-BPS operators are constructed as gauge invariant combinations of any one of these fields, say ϕ, and will be BPS with respect to an R-symmetry, J, which generates an $SO(2) \subset SO(6)$. If Δ is the generator associated to dilatations on the Euclidean plane (R^4), the BPS bound is

$$\Delta = J\,. \tag{1}$$

Anti-BPS operators, constructed from $\bar{\phi}$ satisfy $\Delta = -J$. Given an operator on R^4, the state-operator correspondence of the CFT can be used to give a state of the Lorentzian field theory on $S^3 \times R$. The operator Δ becomes Hamiltonian for the latter. Specifically, given an operator $\mathcal{O}$ in the Euclidean theory, we apply it to the origin, i.e. $\mathcal{O}(0)$, and then conformally map and then Wick rotate to Lorentzian $S^3 \times R$. We will now argue that all the 1/2-BPS states of the theory on $S^3 \times R$ can described in the S-wave reduction of the Yang-Mills theory to a matrix quantum mechanics.

---

[1] Previous work by Sadri and Sheikh-Jabbari [15] has shown that strings stretching between spherical branes in AdS can be realized as solutions to the Born-Infeld action on these branes. Gauss' law emerges in this spacetime picture in the construction of consistent solutions to the equations of motion on a compact space. Since this compact space is not directly part of the manifold on which the Yang-Mills theory is defined, it is very interesting to see how Gauss' emerges from the dual field theory perspective.

The scalar field $\phi(x)$ has a scaling dimension $\Delta = 1$. The Taylor expansion of this field on a surface of fixed time t is

$$\phi(x) = \phi(0) + \sum_{k=1}^{\infty} \frac{1}{k!} \left[\partial_{\mu_1} \cdots \partial_{\mu_k} \phi\right]_{x=0} x^{\mu_1} \cdots x^{\mu_k} \tag{2}$$

where the x^μ are spatial coordinates. Because derivatives commute, the expansion is symmetrized over x^μ, and so this is also an expansion in spherical harmonics (up to traces). Since a derivative ∂_μ has scaling dimension 1, the mth term in the Taylor expansion (or equivalently in a decomposition in spherical harmonics) has a scaling dimension $\Delta = m + 1$. However, the R-charge of all terms in the expansion is still $J = 1$. Thus, the 1/2-BPS states, which must have $\Delta = J$, are all constructed out of the S-wave reduction of ϕ, which we will write as $\phi_{(0)}$.

For example, a 1/2-BPS state corresponding to a supergravity mode with angular momentum k on the S^5 part of the bulk geometry would be given by

$$\mathrm{tr}((\phi^{\dagger}_{0)})^k)|0\rangle\,. \tag{3}$$

Similarly, to construct all 1/2-BPS states of $\mathcal{N} = 4$ Yang-Mills on S^3, we need only the S-wave parts of the spherical harmonic decompositions of all the scalar fields. Thus the study of 1/2-BPS operators relative to a particular $U(1)$ R-symmetry generator J reduces to the study of the quantum mechanics of the mode ϕ_0: a one matrix quantum mechanics.

We must also decompose the gauge fields of the Yang-Mills theory into spherical harmonics. Because of the vector index, only the S-wave of the timelike component A_0 has a coupling to $\phi_{(0)}$. This leaves a $U(N)$ gauged matrix quantum mechanics.

At this point, one could write the effective dynamics of this mode integrating out everything else in the field theory. In the free field limit we simply get a matrix harmonic oscillator. Due to supersymmetry, we expect that this will not change as we increase the coupling constant. Basically, we expect fermions and bosons to cancel and prevent the appearance of an additional potential for the mode $\phi_{0,0}$, and we expect to be able to extrapolate weak coupling results to strong coupling for certain states which are 'close' to these configurations.

The half BPS operators of $\mathcal{N} = 4$ Yang-Mills theory will in be one to one correspondence with the states of this gauged matrix quantum mechanics. Now the problem is to describe a complete basis for these states. As shown in [7], a complete set of such states is given by Schur polynomials in the raising operators. These are constructed as characters of group elements in the different irreducible representations of $U(N)$. An irreducible representation of $U(N)$ built out of m copies of the fundamental representation V is correlated with a representation of the symmetric group S_m. As a result, it can be classified by a Young tableaux with m boxes [2]

---

[2] Some subtleties that arise if the group is $SU(N)$ rather than $U(N)$ have been explained recently

For example, a totally antisymmetric representation of $U(N)$ maps to a Young tableau with one column (the length of which cannot exceed N). A totally symmetric representation of $U(N)$ maps to a Young tableau with one row. These two types of representations have been conjectured to describe the Yang-Mills operators dual to spherical D-branes that expand into S^5 (giant gravitons) and AdS_5 ("dual" giant gravitons) respectively [6, 7]. It has been established that one can correctly reproduce the spectrum of fluctuations of the DBI action for a single maximal size giant graviton [12]. Also, the operators dual to a single maximal giant graviton with some number of attached strings in the plane wave limit have been described in [11] although it has not been shown that the Yang-Mills theory dynamically imposes the Dirichlet and Neumann boundary conditions that appear for open strings in the bulk spacetime description. (We will demonstrate that this indeed happens in Sec. 4.)

Given that 1/2-BPS branes can be described as states in a gauged one matrix model, we can seek a description in terms of eigenvalues of the matrix $\phi_{(0)}$ (these are gauge invariant up to permutations) which effectively form a theory of free fermions in the harmonic oscillator. It turns out that the Young tableaux basis and the basis of Slater determinants of harmonic oscillator wave functions coincide. As shown in [8], there is a beautiful picture in which giant gravitons of energy m (expanding on S^5 arise as a single column Young tableaux with m boxes, and as holes in the Fermi sea of energy m. Conversely, dual giant gravitons of energy m (expanding into AdS_5) arise as a single row Young tableaux with m boxes, and as energy m excitations of a single eigenvalue over the top of the Fermi sea. This is best described in the phase space plane of the eigenvalues, where large collections of fermions put together will form droplets of an incompressible fluid. This same behavior has been seen also in the full supergravity solutions associated to the fermion droplet configurations [9].

One of the key salient features of D-branes is that they give rise to matrix-valued degrees of freedom [16]: it is well-known that the open strings on D-branes realize a gauge theory on the brane worldvolume at low energies. Since the Yang-Mills operators described above are dual to these D-branes, they must also realize this gauge theory if the AdS/CFT correspondence is valid. How and whether this happens is an important question that we seek to answer. The branes arising from the antisymmetric representations (which are dual to giant gravitons expanded into S^5) are the nearest analogue of baryons in $\mathcal{N} = 4$ Yang-Mills. Hence it is extremely interesting to establish whether and how the low-energy dynamics around such baryon-like states realizes a new gauge theory with gauge group unrelated to that of the original Yang-Mills theory.

---

in the paper [29]. In the end, one can write the theory for the $U(N)$ group and notice that the $U(1)$ degrees of freedom factorize. One can proceed by doing the full analysis for $U(N)$ and afterwards remove the unwanted degrees of freedom. These issues are subleading in the $1/N$ expansion, and hence we will ignore them in our analysis.

3 The "Coulomb branch" on a sphere

In the next section we will study the emergence of new gauge symmetries from the dynamics around baryon-like states, but it is useful to first examine a simpler realization of D-branes within Yang-Mills theory. This is simply the familiar physics of the Coulomb branch. In the present case, the novelty is that the gauge theory is on a compact space, so there is no conventional Coulomb branch. However, there is an appropriate analogue [4], the physics of which describes spherical D-branes expanded into AdS$_5$. As argued above, the relevant states can be written in terms of the matrix degrees of freedom of one complex scalar of the Yang-Mills theory. However, to understand the fluctuations of the D-brane we must embed these matrix states into the full $\mathcal{N}=4$ SYM theory.

The SYM action for the $SU(N)$ theory on S^3 is given by

$$\int dt \int_{S^3} dvol \frac{N}{4\pi g^2 N}[\frac{1}{2}(D\phi^i)(D\phi^i) + \frac{1}{4}([\phi,\phi])^2 + \frac{1}{2}\phi^i\phi^i \\ + \text{fermions and gauge fields}] \tag{4}$$

The normalization is chosen such that the gauge curvature does not depend on the coupling. The mass terms of the bosons arises from $R\phi^2$ term arising from conformal coupling to the metric of S^3, The 't Hooft coupling is $g^2N = \lambda$.

Consider a spherical D-brane expanding into AdS$_5$ with a radius of order the AdS scale. Such a brane is stabilized by its angular momentum [3, 4, 5], which we write as $J = Nj$, with j a $O(1)$ constant. As described in [8] and above, such state is created by giving a total energy Nj to a single eigenvalue of the S-wave of a complex scalar field, say $\phi = (\phi^1 + i\phi^2)/\sqrt{2}$. The semiclassical description of such a state is

$$\phi(x) = \text{diag}(A, 0, 0, \dots 0)e^{-it} \tag{5}$$

exactly as previously proposed by [4]. Matching the energy $jN = \int_{S^3} dvol \frac{N}{4\pi\lambda}|A|^2$ gives us the semiclassical amplitude for the field

$$|A|^2 = \frac{4\pi\lambda j}{\text{Vol}(S^3)} \tag{6}$$

Since this depends only the 't Hooft coupling, such states are well defined in the large N 't Hooft limit.

Expanding around this semiclassical state, the n$^{\text{th}}$ spherical harmonic (i.e. the $(n/2, n/2)$ representation) of off-diagonal terms of ϕ^i for $i = 3, \dots 6$ wil have a mass:

$$m = \sqrt{1 + n + \frac{4\pi\lambda j}{\text{Vol}(S^3)}}\,. \tag{7}$$

This is the energy of the state on the cylinder – on the plane this would map to the conformal dimension. This is because the energy operator on S^3 is related to the radial quantization of the Euclidean field theory on R^4. Thus, the effective description of the spherical D-brane in AdS$_5$ in the CFT is as a (time dependent) Higgs mechanism which breaks the gauge group $SU(N)$ to $SU(N-1)\times U(1)$.

By similar reasoning we can see the dual Yang-Mills realization of the enhanced gauge symmetry on coincident D-branes in AdS$_5$. To describe two D-branes in AdS, following [8] we must excite two eigenvalues:

$$\phi \sim \begin{pmatrix} A_1 & 0 & 0 & \dots \\ 0 & A_2 & 0 & \dots \\ 0 & 0 & 0 & \dots \\ \vdots & \vdots & \vdots & \ddots \end{pmatrix} \tag{8}$$

breaking the symmetry down to $U(1)\times U(1)\times SU(N-2)$ The branes are coincident in this semiclassical description if $A_1 = A_2$ so that $U(1)\times U(1)$ is enhanced $U(2)$. The phase of the eigenvalue is associated to the position of the brane along the circle on the bulk S^5 along which the brane is moving. Thus, in this simple example, the gauge symmetry arising from D-branes in AdS$_5$ is embedded within the original gauge symmetrty of the dual and is local in the original S^3 on which the latter is defined. For example, Gauss' law on the D-brane is implemented trivially because the $SU(N)$ theory dual to AdS$_5$ implements Gauss' law.

Vibrational spectrum of AdS_5 branes: The fluctuation spectrum of the massless modes of spherical branes in AdS$_5$ was computed in [17]. Surprisingly, the spectrum turns out to be independent of the angular momentum and size of the brane. For example, translating into Yang-Mills variables, the fluctuations of the transverse scalars of the brane in spin $(n/2, n/2)$ spherical harmonic should be reperesented by Yang-Mills operators have a conformal dimension with conformal dimension $n+1$. Observe that at large 't Hooft coupling λ the Yang-Mills configuration corresponding to a single brane on AdS$_5$ (5) involves the Coulomb branch with gauge group broken to $SU(N-1)\times U(1)$. As described above, at large λ, the $U(1)$ is decoupled from $SU(N-1)$ since all off-diagonal terms are very massive, and all low energy states can be decomposed under these groups. The transverse fluctuations of the brane in AdS are represented in the Yang-Mills theory by modes of the scalars ϕ^i for $i = 3, \dots 6$ that are neutral under both $U(1)$ and $SU(N-1)$ – namely, these are diagonal fluctuations of the form

$$\phi^i \sim \begin{pmatrix} a^\alpha & 0 & \cdots \\ 0 & 0 & \cdots \\ 0 & 0 & \cdots \\ \vdots & \vdots & \ddots \end{pmatrix} \tag{9}$$

The spatial $SO(4)$ rotation group of the field theory maps onto the $SO(4)$ rotation group of the brane in the bulk. Decomposing the ϕ^i into spherical harmonics, the spin $(n/2, n/2)$ representation will then have dimension $(n+1)$, matching the bulk D-brane results [17]. Supersymmetry then generates the remainder of the spectrum. We might worry that the free field result might experience large quantum corrections, because these fluctuations are not BPS. However, one can argue that the states in question arise as would-be goldstone modes associated to the spontaneous breaking of the $SO(6)$ symmetry and therefore their masses are protected. This is similar to arguments given in [18] to reproduce the spectrum of the string on the pp-wave. In both cases, if one takes the Hamiltonian as $H_{eff} = \Delta - J$, the Hamiltonian is no longer $SO(6)$ symmetric, although the Casimir of $SO(6)$ does commute with H_{eff} and can be used to classify states. This is why the would-be Goldstone modes are massive, but their masses are protected.

It is also interesting that the result is independent of the size of the brane, since at large radius one would expect a blue-shift which would increase the total energy of these states. However, these states are massless on the D-brane, and the blue-shift is offset by the fact that that the particles move on a bigger sphere, so that their energy is reduced by the increase in size of the brane. If the particles were massive, this would not happen, because we would still have the rest mass of the particle.

Note also that the large giant gravitons expanded into AdS have a worldvolumes that lie "close" to the AdS boundary. This is why local physics on such branes will be essentially described by local effective dynamics in the boundary theory also. For some calculations we can even ignore the curvature of the S^3, if we are considering very massive states on the D-brane worldvolume, like massive strings.

Massive strings on AdS_5 branes: There is an attractive interpretation of the massive off-diagonal modes with masses (7) in terms of massive excitations of the strings on an AdS$_5$. Consider a single brane state (5) which breaks the Yang-Mills gauge group to $SU(N-1) \times U(1)$. Here the $SU(N-1)$ dynamics in the gauge theory is interepreted as reproducing the gravitational physics of the semiclassical AdS space in which a single probe brane described by the $U(1)$ is embedded. In order to construct gauge invariant massive excitations of the ϕ^i, one needs oscillators of the form

$$\phi^i \sim \begin{pmatrix} 0 & a^\alpha & \cdots \\ b_\alpha & 0 & \cdots \\ \vdots & \vdots & \ddots \end{pmatrix} \tag{10}$$

so that gauge invariant states can be constructed as

$$\sum b^\dagger_\alpha (a^\alpha)^\dagger |0>_A \tag{11}$$

More generally one can build states including "gluons" of the $SU(N-1)$ dynamics. This construction is interpreted as a realization of Gauss's law on the spherical brane in AdS. To see this, recall that since the brane is compact, the two oppositely charged ends of an open string must end on it. Since the string is oriented, we can interpret the a^α as (say) the outgoing end of the open string and b_α as the incoming piece. The off-diagonal oscillators in the Yang-Mills are charged under the $U(1)$ which describes the probe brane and also under the $SU(N-1)$ which realizes the AdS dynamics. Pictorially the off-diagonal excitations leave the brane (the top left eigenvalue), explore the bulk AdS (the $SU(N-1)$ part of the ϕ^i matrix) and then return to the brane. This is similar to the description of strings on branes in the Poincare patch of AdS space that are described in terms of the Coulomb branch of a dual theory on a plane.

In the Yang-Mills theory, eq. (7) indicates that such excitations will have a mass of order $\sim \sqrt{\lambda j}$ at large λ. When $\lambda \sim g^2 N$ is large, the dual spacetime has a very low curvature and thus the strings on a large spherical D-brane are essentially moving in flat space. The proper energy of such a string (translated CFT units by multiplying by the AdS scale) will go as $E_p \sim \sqrt[4]{\lambda}$. To relate this to the dual CFT we must multiply by the redshift factor arising from the relation between coordinate and global time. The metric in global coordinates of AdS_5 is given by

$$ds^2 = -(1+r^2)dt^2 + \frac{1}{1+r^2}dr^2 + r^2 d\Omega_3^2 \tag{12}$$

The proper energy at position r, E_p is related to energy measured as $E \sim \sqrt{1+r^2}E_p$. Recall that the string is question is attached to brane with angular $J = Nj$, and such branes have a radius $r^2 = j$ [5, 4]. Thus the energy of the string in CFT units is predicted by supergravity analysis to be $E \sim \sqrt{j}\sqrt[4]{\lambda}$. This disagrees with the mass of $\sqrt{j\lambda}$ (7) predicted in the free field analysis on the Yang-Mills theory although the $\sqrt{j}$ dependence agrees. Notice that agreement would be obtained if a full quantum treatment in Yang-Mills theory simply led to the replacement $\lambda \to \sqrt{\lambda}$. This has been seen before in AdS/CFT Wilson loop calculations [19], and the similarity is not accidental since those computations were also dealing with the physics of the Coulomb branch, albeit on a plane.

4 "Baryons" as D-branes

In the previous section we argued that many properties of spherical branes in AdS_5 and the open strings on them are simply understood in terms of the analog of a Coulomb branch on a sphere. In this section we turn to a more challenging problem – the description of spherical branes that have expanded in the S^5 (giant gravitons). It was proposed in [6] that such states are described in the dual field theory by baryon-like operators – determinants and subdeterminants of scalar fields. To be specific let X, Y, Z be three complex scalar fields constructed from the six real chiral scalars of the Yang-Mills theory ϕ^i as $X = \frac{\phi^1 + i\phi^2}{\sqrt{2}}$, $Y = \frac{\phi^3+i\phi^4}{\sqrt{2}}$ and $Z = \frac{\phi^5+i\phi^6}{\sqrt{2}}$. The giant gravitons are described by operators

$$\mathcal{O}_M = \epsilon^{j_1 \cdots j_M i_{M+1} \cdots i_N}_{i_1 \cdots i_M i_{M+1} \cdots i_N} Z^{i_1}_{j_1} \cdots Z^{i_M}_{j_M} \tag{13}$$

Here $M = N$ for a maximal size giant graviton. The group theoretic arguments of [7] and the matrix model analysis of [8] confirm this.

It has also been shown that the Yang-Mills theory contains excitations with the correct charges and conformal dimensions to describe strings propagating on the giant gravitons in spacetime [11]. For example, strings propagating on a maximal giant graviton are proposed to be described by the operators like [11]:

$$\mathcal{O}_k^{Z,Y,X} = \epsilon_{i_1\cdots i_N}^{j_1\cdots j_N} Z_{j_1}^{i_1} \cdots Z_{j_{N-1}}^{i_{N-1}} (Y^k X Y^{J-k})_{j_N}^{i_N} \tag{14}$$

$$\mathcal{O}_k^{Z,Y,Z} = \epsilon_{i_1\cdots i_N}^{j_1\cdots j_N} Z_{j_1}^{i_1} \cdots Z_{j_{N-1}}^{i_{N-1}} (Y^k Z Y^{J-k})_{j_N}^{i_N} \tag{15}$$

Here the string of Ys builds up the worldvolume of a string excitation with momentum J in a manner similar to the description of strings on pp-waves [18] and on dibaryon states [20]. The additional insertions of the "impurities" X in (14) and Z in (15) correspond further oscillator excitations of the string. As described in the dictionary given in [11], (14) should correspond to a fluctuation along the brane which therefore has Neumann boundary conditions, while (15) represents a transverse fluctuation that should have Dirichlet boundary conditions. The missing piece of logic in demonstrating that "baryons" such as (13) are actually D-branes is to show these Neumann and Dirichlet boundary conditions emerge dynamically in the Yang-Mills theory. We will show this in the plane wave limit, where it is easy to compare with results for open string spectra on D-branes [24, 25, 26, 27]

To do this, we must compute the normalized matrix elements

$$M_{ij} = \frac{\langle \mathcal{O}_i^*(x)\mathcal{O}_j(0)\rangle_{free+interacting}}{\sqrt{\langle \mathcal{O}_i^*(x)\mathcal{O}_i(0)\rangle_{free}}\sqrt{\langle \mathcal{O}_j^*(x)\mathcal{O}_j(0)\rangle_{free}}} \tag{16}$$

where $i, j = 1 \cdots J$ represent the position of the impurity within the string. The relevant part of the $\mathcal{N} = 4$ SYM action is

$$S = \frac{1}{2\pi g_s}\int d^4x \, \mathrm{tr}\Big(\frac{1}{2}F_{\mu\nu}F^{\mu\nu} + D_\mu Z D^\mu \overline{Z} + D_\mu Y D^\mu \overline{Y} + D_\mu X D^\mu \overline{X} + V_D + V_F\Big) \tag{17}$$

Where the D-term potential and the F-term potentials are

$$V_D = \frac{1}{2}\mathrm{tr}|[X,\overline{X}] + [Y,\overline{Y}] + [Z,\overline{Z}]|^2 \tag{18}$$

$$V_F = 2\mathrm{tr}(|[X,Y]|^2 + |[X,Z]|^2 + |[Y,Z]|^2) \tag{19}$$

According to the argument in Appendix B in [21], The D-term and gluon exchange cancel at one loop order (this is based on techniques in previous papers [22, 23]), so to this order we only need to consider the contributions from F-term. The scalar propagators are

$$\langle Z_i^j(x)\overline{Z}_k^l(0)\rangle = \langle Y_i^j(x)\overline{Y}_k^l(0)\rangle = \langle X_i^j(x)\overline{X}_k^l(0)\rangle = \delta_i^l\delta_k^j\frac{2\pi g_s}{4\pi^2}\frac{1}{|x|^2}, \tag{20}$$

4.1 Neumann

The matrix (16) M_{ij} consists of a free part, which is easy to compute, and an interacting part. The norms of the operators (14) are

$$\langle (\mathcal{O}_k^{Z,Y,X}(x))^* \mathcal{O}_k^{Z,Y,X}(0)\rangle_{free} = (N-1)!\ N!^2 \frac{1}{|x|^{2(N+J)}} N^J (\frac{2\pi g_s}{4\pi^2})^{N+J} \equiv \frac{C}{|x|^{2\Delta}}, \tag{21}$$

where $C \equiv (N-1)!\ N!^2 N^J(\frac{2\pi g_s}{4\pi^2})^{N+J}$ and $\Delta = (N+J)$. The factor of $(N-1)!$ counts the number of contractions between the Zs. $N!^2$ is the result of contracting four ϵ tensors in pairs and N^J results from J loops from contracting the Ys and X planarly. It is obvious that the free off-diagonal part will be suppressed by powers of N since we can not contract planarly, so the free part in M_{ij} is just identity matrix.

$$M_{ij}^{free} = \delta_{ij} \tag{22}$$

To calculate the one-loop interacting piece we insert the operator $-\frac{1}{2\pi g_s} V_F$ in the correlator, and then integrate the three point function over the position of the inserted operator. The leading large N contributions come from $-2tr([X,Y][\overline{X},\overline{Y}])$ in the F-term.[3] (The calculation is very similar to those made with BMN operators in pp-wave settings [18]). First consider the diagonal part of M_{ij}. For $1 \le k \le J-1$, following the calculations in the appendix of [11] we find

$$\begin{aligned} &\langle \mathcal{O}_k^{Z,Y,X}(x)^* \mathcal{O}_k^{Z,Y,X}(0)\rangle_{one-loop} \\ = &\int d^4y \langle \mathcal{O}_k^{Z,Y,X}(x)^* \mathcal{O}_k^{Z,Y,X}(0) = \Big(-\frac{2Ng_s}{\pi}\Big)\frac{C}{|x|^{2\Delta}}\log(|x|\Lambda) \end{aligned} \tag{23}$$

For $k=0$ or $k=J$ only $\mathrm{tr}(XY\overline{YX})$ or $\mathrm{tr}(YX\overline{XY})$ contribute, so we have one half of the result

$$\begin{aligned} &\langle \mathcal{O}_0^{Z,Y,X}(x)^* \mathcal{O}_0^{Z,Y,X}(0)\rangle_{one-loop} = \langle \mathcal{O}_J^{Z,Y,X}(x)^* \mathcal{O}_J^{Z,Y,X}(0)\rangle_{one-loop} \\ = &\Big(-\frac{Ng_s}{\pi}\Big)\frac{C}{|x|^{2\Delta}}\log(|x|\Lambda) \end{aligned} \tag{24}$$

Now we compute off-diagonal piece. The calculation is similar to above except $\mathrm{tr}(XY\overline{XY})$ or $\mathrm{tr}(YX\overline{YX})$ contribute, so we have opposite sign contribution. We find (for $1 \le k \le J$)

$$\langle \mathcal{O}_{k-1}^{Z,Y,X}(x)^* \mathcal{O}_k^{Z,Y,X}(0)\rangle_{1-loop} \langle \mathcal{O}_k^{Z,Y,X}(x)^* \mathcal{O}_{k-1}^{Z,Y,X}(0)\rangle_{1-loop} = \Big(\frac{Ng_s}{\pi}\Big)\frac{C}{|x|^{2\Delta}}\log(|x|\Lambda) \tag{25}$$

---

[3] There is also a non-vanishing constant contribution from interaction of $Z's$ and $Y's$ as shown in appendix in [11], but this contribution is of order g_s, so is much smaller in planar limit than the contribution of order $g_s\frac{N}{J^2}$ we consider here. This small contribution is argued to be related to one-loop open strings effect [11], which we will not discuss here.

In summary, the matrix of overlaps (16) at 1-loop is

$$M_{one-loop} = -\frac{Ng_s}{\pi}\log(|x|\Lambda)\begin{pmatrix} 1 & -1 & 0 & 0 & \cdots \\ -1 & 2 & -1 & 0 & \cdots \\ 0 & -1 & 2 & -1 & \cdots \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & -1 & 1 \end{pmatrix} \tag{26}$$

By diagonalizing this one-loop planar mixing matrix we can obtain a basis of energy eigenstates. As argued in [27] the eigenstates with eigenvalue n are superpositions of the operators (14) with coefficients $\cos(\pi nk/J)$. The cosine factor directly describes a fluctuation of the string with Neumann boundary conditions on the brane. The 1-loop anomalous dimensions of the orthogonal operators are extracted from the diagonalized overlap matrix by removing the log and diving by 2.

4.2 Dirichlet

We can repeat the analysis for the operators (15). Everything goes through as above, if the insertion Z is not at the edges. However, if Z is at the edge of the string of Ys, say at $k = 0$ we can immediately see that the operator changes character [12]. It factorizes as

$$\mathcal{O}_0^{Z,Y,Z} = \epsilon_{i_1\cdots i_N}^{j_1\cdots j_N} Z_{j_1}^{i_1}\cdots Z_{j_{N-1}}^{i_{N-1}}(ZY^J)_{j_N}^{i_N} = \frac{1}{N}(N!\det(Z))\mathrm{tr}(Y^J) \tag{27}$$

where $N!\det(Z) = \epsilon_{i_1\cdots i_N}^{j_1\cdots j_N} Z_{j_1}^{i_1}\cdots Z_{j_N}^{i_N}$. We interpret this as saying that state has factorized in a giant graviton ($\det Z$) with a nearby closed string ($\mathrm{tr}(Y^J)$). The norm is

$$\langle(\mathcal{O}_0^{Z,Y,Z}(x))^*\mathcal{O}_0^{Z,Y,Z}(0)\rangle_{free} = JN!^3N^{J-2}(\frac{2\pi g_s}{4\pi^2})^{N+J}\frac{1}{|x|^{2(N+J)}} \tag{28}$$

The free off-diagonal part is also suppressed by powers of N and the free part matrix M_{ij} is identity matrix $M_{ij}^{free} = \delta_{ij}$ as in the case of Neumann boundary condition.

Now consider one-loop part of the matrix element involving the $k = 0, J$ impurities.

$$\langle\mathcal{O}_0^{Z,Y,Z}(x)^*\mathcal{O}_0^{Z,Y,Z}(0)\rangle_{one-loop} = \int d^4y\langle\mathcal{O}_0^{Z,Y,Z}(x)^*\mathcal{O}_0^{Z,Y,Z}(0)(\frac{1}{\pi g_s})\mathrm{tr}([Y,Z][\overline{Y},\overline{Z}])(y)\rangle \tag{29}$$

The leading large N contribution turns out to be

$$\begin{aligned}\langle\mathcal{O}_0^{Z,Y,Z}(x)^*\mathcal{O}_0^{Z,Y,Z}(0)\rangle_{1-loop} &\sim (N-1)!^3\langle\mathrm{tr}(Z\overline{Z})\mathrm{tr}(Y^J)\mathrm{tr}(\overline{Y}^J)\mathrm{tr}([Y,Z][\overline{Y},\overline{Z}])\rangle \\ &\sim (N-1)!^3J^2N^{J+1}\end{aligned} \tag{30}$$

So the ratio between the free and interacting parts

$$\frac{\langle\mathcal{O}_0^{Z,Y,Z}(x)^*\mathcal{O}_0^{Z,Y,Z}(0)\rangle_{one-loop}}{\langle(\mathcal{O}_0^{Z,Y,Z}(x))^*\mathcal{O}_0^{Z,Y,Z}(0)\rangle_{free}} \sim J\frac{g_s}{\pi}\log(|x|\Lambda) \tag{31}$$

This is suppressed compared to the matrix elements of the overlap matrix M for impurities in the interior which are all of order N.

Finally, we compute the off-diagonal elements of M connecting the $k=0,J$ impurities at the edge of the string and impurities in the interior $\langle \mathcal{O}_0^{Z,Y,Z}(x)^* \mathcal{O}_1^{Z,Y,Z}(0)\rangle_{1-loop}$. (The overlap with k deeper in the interior is further suppressed.) The leading large N power is

$$\begin{aligned}\langle \mathcal{O}_0^{Z,Y,Z}(x)^* \mathcal{O}_1^{Z,Y,Z}(0)\rangle_{1-loop} &\sim (N-1)!^3 \langle \mathrm{tr}(\overline{Y}^J)\mathrm{tr}(\overline{Z}YZY^{J-1})\mathrm{tr}([Y,Z][\overline{Y},\overline{Z}])\rangle \\ &\sim J(N-1)!^3 N^{J+2} \end{aligned} \tag{32}$$

So in the leading large N order

$$\frac{\langle \mathcal{O}_0^{Z,Y,Z}(x)^* \mathcal{O}_1^{Z,Y,Z}(0)\rangle_{1-loop}}{\sqrt{\langle \mathcal{O}_0^{Z,Y,Z}(x)^* \mathcal{O}_0^{Z,Y,Z}(0)\rangle_{free}}\sqrt{\langle \mathcal{O}_1^{Z,Y,Z}(x)^* \mathcal{O}_1^{Z,Y,Z}(0)\rangle_{free}}} \sim \frac{g_s}{\pi}\sqrt{NJ}\log(|x|\Lambda) \tag{33}$$

In summary the one-loop overlap matrix (16) is

$$M_{1-loop} = -\frac{Ng_s}{\pi}\log(|x|\Lambda)\begin{pmatrix} O(\frac{J}{N}) & O(\sqrt{\frac{J}{N}}) & 0 & 0 & \cdots \\ O(\sqrt{\frac{J}{N}}) & 2 & -1 & 0 & \cdots \\ 0 & -1 & 2 & -1 & \cdots \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & O(\sqrt{\frac{J}{N}}) & O(\frac{J}{N}) \end{pmatrix} \tag{34}$$

At large N the contributions from the edges of the string $k=0,J$ decouple which is in agreement with the observation at the beginning of this section that these operators describe a state with a giant graviton and separate closed string. It was argued in [27] that a matrix of overlaps of the form of the remainder of M after eliminating $k=0,J$ diagonalizes to describe string excitations with Dirichlet boundary conditions on a brane, namely excitations where the endpoints do not move.

4.3 Open strings on smaller D-branes

Above we were discussing the leading large N contributions in the Yang-Mills to the anomalous dimension of operators dual to excitations of strings attached to a maximal size D-brane. As mentioned we neglected an $O(1)$ 1-loop piece which is, however, the dominant contribution to the anomalous dimension of the ground state of the string. In [11] this contribution was shown to be

$$\frac{(J-1)g_s}{\pi}. \tag{35}$$

This contribution to the dimension should arise in spacetime from a one-loop open string effect since it has one less power of N than the leading terms in the dimension of excited strings [11]. Here we study the 1-loop contribution to the dimension of operators describing the ground of a string on a giant graviton of less than maximal size, namely $\mathcal{O}_M$ in (13) with $M < N$. Quite surprisingly, we find the one-loop anomalous dimension of the ground state of the string grows like $\frac{(N-M)g_s}{\pi}$. The spacetime interpretation of this is not entirely clear, but the result will be of use in later sections.

The dual operator of an open string attached to a non-maximal giant graviton is [6, 7, 11]

$$\mathcal{O} \equiv \epsilon^{j_1 \cdots j_M}_{i_1 \cdots i_M} Z^{i_1}_{j_1} \cdots Z^{i_{M-1}}_{j_{M-1}} (Y^J)^{i_M}_{j_M} \tag{36}$$

We compute the free and one-loop two point function $\langle \mathcal{O}\overline{\mathcal{O}} \rangle$ in the leading order at large N and M, but we do not assume $N-M$ to be large.[4] After calculations using formulae in appendix A, we find the free and one-loop two point function.

$$\begin{aligned} \langle \mathcal{O}(x)\overline{\mathcal{O}}(0)\rangle_{free} &= N^{J+1}\frac{(N-2)!(M-1)!^2(M-1)}{(N-M)!}(\frac{g_s}{2\pi|x|^2})^{M+J-1} = \frac{C}{|x|^{2\Delta}} \\ \langle \mathcal{O}(x)\overline{\mathcal{O}}(0)\rangle_{1-loop} &= -\frac{2g_s}{\pi}(N-M+J-1)\frac{C}{|x|^{2\Delta}}\log(|x|\Lambda) \end{aligned} \tag{37}$$

Here $\Delta = M+J-1$ is the free field conformal dimension. From (37) and (37) the one-loop anomalous dimension is

$$\delta\Delta_{one-loop} = \frac{(N-M+J-1)g_s}{\pi}\,. \tag{38}$$

So when $M = N$ so that the brane is of maximal size we reproduce the result $\frac{(J-1)g_s}{\pi}$ in [11].

5 Multi-brane states and Gauss' Law

The arguments in [11] and in Sec. 4 together establish that determinants and sub-determinants are D-brane operators of Yang-Mills theory, supporting open string excitations at large N. A system of G such D-branes should dynamically realize a new gauge theory associated with the low-energy excitations of these strings. This local gauge theory will be local on an emergent space, the D-brane worldvolume, which is not embedded in the space on which the original Yang-Mills theory is defined. To study this we must first propose a description of a multi-D-brane state. An approximately orthogonal basis of low conformal dimension states (corresponding to supergravity particles) can be constructed from products of single-trace operators, with number of traces being an approximate quantum number counting the number of particles [2]. Thus, a natural guess for an operator describing a system of Yang-Mills D-branes is a product of sub-determinants, with the open strings stretching between the branes represented as defects with indices entangled between the D-brane operators. Since the D-branes are compact, Gauss' law should be realized by the restriction that as many strings should start as end on any given brane in order that the net charge on the brane be zero.

---

[4] Here we assume $J > 1$. When $J = 1$ additional terms contribute, and the one-loop anomalous dimension cancels and does not grow. This is just as expected since when $J = 1$ this operator is a BPS operator so there should be no anomalous dimension.

It will turn out that for a state with two branes, one of them of maximal size, the naive product operator is the correct one. It is instructive to first see how Gauss' Law is realized in this special case. Naively one would expect four states – one string on each brane and two (oriented) strings running between them. However, Gauss' Law forbids the strings between the branes.

As in the previous section, a string attached to a single brane is described by [11]

$$\mathcal{O} \equiv \epsilon^{j_1 j_2 \cdots j_M}_{i_1 i_2 \cdots i_M} Z^{i_1}_{j_1} Z^{i_2}_{j_2} \cdots Z^{i_{M-1}}_{j_{M-1}} (Y^J)^{i_M}_{j_M} \,. \tag{39}$$

The natural guess for the operator describing a maximal brane and a smaller brane with a string attached to it is:

$$\mathcal{O}_{22} \equiv \epsilon^{j_1 \cdots j_N}_{i_1 \cdots i_N} Z^{i_1}_{j_1} \cdots Z^{i_N}_{j_N} \epsilon^{l_1 \cdots l_M}_{k_1 \cdots k_M} Z^{k_1}_{l_1} \cdots Z^{k_{M-1}}_{l_{M-1}} (Y^J)^{k_M}_{l_M} \,. \tag{40}$$

As pointed out in [11], we can construct another operator from the above by exchanging the upper (or lower) index of Y^J with one of the Z's in the other brane. This gives

$$\mathcal{O}_{12} \equiv \epsilon^{j_1 \cdots j_N}_{i_1 \cdots i_N} Z^{i_1}_{j_1} \cdots Z^{k_M}_{j_N} \epsilon^{l_1 \cdots l_M}_{k_1 \cdots k_M} Z^{k_1}_{l_1} \cdots Z^{k_{M-1}}_{l_{M-1}} (Y^J)^{i_N}_{l_M} \,. \tag{41}$$

The operator thus constructed looks like a single open string stretching between two branes. This would violate Gauss' Law.

Now observe that in $\mathcal{O}_{12}$ if $k_M \neq i_N$, then there is an $x < N$ such that $k_M = i_x$. There will be two Z's in the operator with the indices $Z^{i_x}_{j_x}$ and $Z^{i_x}_{j_N}$. These terms will then be cancelled by the antisymmetrization in the summation of j's. We are left with terms that have $k_M = i_N$. It is then easy to see that these two operators are related by

$$\mathcal{O}_{12} = \frac{1}{N} \mathcal{O}_{22}. \tag{42}$$

This is because in the operator $\mathcal{O}_{22}$ there must be a $1 \leq x \leq N$ that $i_x = k_M$. We have N choices of x and each of them gives us the result $\mathcal{O}_{12}$ according the above argument. So we see that a combinatorial identity causes a state that would apparently violate Gauss' Law to be equivalent to a linear combination of states that do not do so.

We would like to go beyond this simple special case to a general analysis that applies to arbitrary systems of branes and open strings. In general, it turns out that products of antisymmetric representations are not a useful orthogonal basis – indeed, they decompose into sums of irreducible representations that have non-zero overlaps – and they do not obviously realize Gauss' Law. Below, following ideas in [7, 8], we describe an alternate basis of operators for branes with open string excitations and show that Gauss' law is realized almost automatically.

5.1 Multi-brane states

It is helpful to start with the free fermion description of half-BPS states. The fermions wave functions are identified with characters of different irreps of $U(N)$.[5] Recall from Sec. 2 that k coincident D-branes expanding onto S^5 are described a fermi sea with k holes, and that this is a configuration corresponding to a k column Young tableau. We can think of these as tensors in the variable Z^i_j, where the Young tableau realizes the symmetry under permutations of the upper matrix indices of Z. Since the Z are indistinguishable bosons, the upper and lower indices have to transform identically under permutations (see, e.g., [28]). In other words $Z^{i_1}_{j_1} Z^{i_2}_{j_2}$ is invariant under the double exchange of sub-indices on the labels $1 \leftrightarrow 2$.

When the upper and lower Young tableaux are the same (as they are for a state created from a product of Zz only), a $U(N)$ singlet is formed by taking a trace, i.e., contracting all upper indices with all lower indices. For more general states that are not half BPS, we must add more matrix degrees of freedom in addition to the Z field. In particular, we will think of open string states as words constructed from the alphabet of field variables and then treat them as "composite" matrices with one upper and one lower index per string $(M_\alpha)^i_j$. This leads to a partonic description of the string in the free field limit. To build states of strings on D-branes, we separately tensor the upper and lower indices of the D-brane operator with the (multiple) string states, and then decompose the result in representations of $U(N)$. Roughly, this means that we start with the Young tableau for the D-branes and add to it an additional box for each string state we are considering. In this picture the shape of the tableau we start with defines the system of branes and adding strings changes the shape of the tableau. (The next section will take a slightly different approach which is essentially equivalent when the branes are large.)

Since the composite string degree of freedom M can be distinguished from Z, the upper and lower indices of M need not be in the same box of a Young tableau – the trace can be non-vanishing even if the indices are "entangled" in this way. Thus, for each state, we can consider a double Young tableaux representation, where we keep track of both upper and lower indices Pictorially, the string M begins (ends) on the brane represented by the Young tableau column which contains the box associated to the upper (lower) index of M. For example, see Fig. 1. In this case, the upper and

---

[5] Of course we should really be using $SU(N)$ in order to apply the AdS/CFT correspondence. However, the differences between the two analyses are suppressed by powers of N. Also, one can do the calculations in $U(N)$ and systematically eliminate the $U(1)$ diagonal degrees of freedom, since they are decoupled. Thus, in the remainder of this paper we will neglect this issue which been explored in [29].

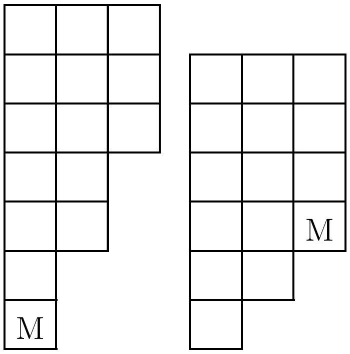

Figure 1: One string beginning in one giant graviton and ending in another one

lower indices correspond to different Young tableaux. If one tries to make a gauge invariant state by contracting upper and lower indices one gets zero, since there is no $U(N)$ singlet associated to the tensor product of these two irreducible representations. This is expected by Gauss' Law, which forbids a single string stretched between two distinguishable compact branes. However, we can consider adding more strings as in Fig. 2. We see in this case that the tableaux of upper and lower indices have the same shape but the boxes corresponding to upper and lower indices of an individual string might be different. So now when we contract the indices there is a singlet, which is consistent with Gauss' Law: a pair of oppositely oriented strings can run between two compact branes.

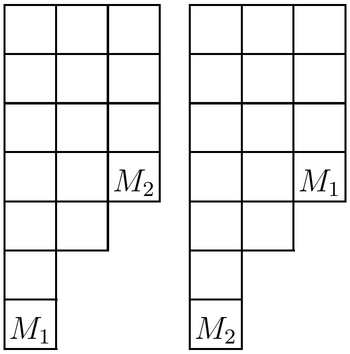

Figure 2: Two strings stretching between two giants with opposite orientations

In this construction, the requirement that operators be $U(N)$ invariant forces appropraite contractions of upper and lower indices to obtain singlet states. This forces the upper and lower Young tableaux to have the same shape, or equivalently, to have the same number of strings starting and ending on each brane. This is Gauss' law. The argument can be extended to multiple D-branes expanding into AdS_5 as well. There, strings beginning and ending on one of those giants will add boxes to Young tableaux rows that represent D-branes. This symmetry between the exchange of columns and rows in the description of states amounts to particle/hole duality and suggests that whatever happens for the AdS giants also happens for the S^5 giants.

At this point, it would be convenient if we could perform all the calculations with the given states above. However, we have not found a way to do that systematically. There is another basis of states which seems to be equivalent to the one described above, and we will work with it in the following sections because the combinatorics is easier to handle. We give some arguments suggesting the equality of the two prescriptions. It is clear that the basis of operators described above seems to have the right intuition regarding strings stretching between different D-branes, so we will assert at this point without proof that it is the right solution to the problem of classifying all strings stretching between D-branes and counting them.

5.2 Strings stretching between D-branes

So far, we have seen how to build the states that are associated to different strings stretching between D-branes from a "pictorial" point of view. Now we want to be systematic and have not found a way to do it in the basis mentioned before. For this purpose, as explained above, we will use a slightly different formalism from the previous section: (a) we will fix the tableau shape and replace some boxes (in arbitrary places on the Young diagram) with open strings (rather than adding open string boxes, thus changing the tableau shape), and (b) we will only have a tableau permuting the lower $U(N)$ indices (this is essentially considering the relative permutation between upper and lower indices in the methods of the previous section). The results of the two formalisms hopefully will be identical and cover all possible operators near the giant graviton configuration systematically when the number of boxes is of order N.

The basic tool that we will use is the isomorphism between gauge invariant operators of unitary groups and representations of the permutation group S_n. (See [30], [7] and references therein.)

Recall that every irreducible representation of S_n is associated to a Young diagram with n boxes. A tableau is constructed by filling the diagram with numbers $1 \cdots n$. Let $H \in S_n$ be the *horizontal subgroup* of permutations of $1 \cdots n$ that preserves the rows of a Young diagram, and let $V \in S_n$ be the column-preserving *vertical subgroup*. A *Young element* of the group algebra of S_n is associated to a Young tableau as

$$c_{\text{Young}} = \sum_{p \in H} \sum_{q \in V} (-)^{\text{sign}(q)} p \cdot q \tag{43}$$

where sign(q) is ± 1 for even/odd permutations. For example, the Young element of Fig. a is given by

$$[I + P_{12}] \cdot [I - P_{13}] = I + P_{12} - P_{13} - P_{12} P_{13}$$

where P_{ab} exchanges the labels a and b. The $n!$ Young elements associated to a given Young diagram are linearly dependent and span a sub-algebra of the complete group algebra. A complete basis for the group algebra is obtained by taking the union of the sub-algebra bases obtained for each irreducible representaion of S_n.

Now as in [7], given a Young tableau of S_n and related Young elements we can contruct a gauge invariant operator from n unitary matrices $\Phi_1, ..., \Phi_n$ as

$$\mathcal{O}_{Young} = \sum_{i_1,...,i_n=1}^{N} \sum_{p\in H} \sum_{q\in V} (-)^{\mathrm{sign}(q)} (\Phi_1)^{i_1}_{i_{p\cdot q(1)}} (\Phi_2)^{i_2}_{i_{p\cdot q(2)}} ... (\Phi_n)^{i_n}_{i_{p\cdot q(n)}} \ . \tag{44}$$

For example, the Young tableau (a) in Fig.3 will give

$$\mathcal{O} = \mathrm{Tr}\,\Phi_1\,\mathrm{Tr}\,\Phi_2\,\mathrm{Tr}\,\Phi_3 - \mathrm{Tr}\,\Phi_1\Phi_3\,\mathrm{Tr}\,\Phi_2 + \mathrm{Tr}\,\Phi_1\Phi_2\,\mathrm{Tr}\,\Phi_3 - \mathrm{Tr}\,\Phi_1\Phi_3\Phi_2$$

If we set all $\Phi_i = \Phi$, a single complex scalar of the $\mathcal{N} = 4$ Yang-Mills theory, $\mathcal{O}_{Young}$ in (44) will be a $\frac{1}{2}$-BPS operator as proposed in [7].[6]

Following [6, 7, 12] we will interpret such 1/2-BPS tableaux that are largely antisymmetric, with columns of length of order the rank of the $SU(N)$ gauge group as collections of spherical D-branes that have expanded into the S^5 factor of $\mathrm{AdS}_5 \times S^5$. Columns of length larger than N cannot exist because of antisymmetry between the rows. One very special and simple case is the product of a single-column tableau of length N and any other single column tableau – this is simply a joined 2-column tableau by the standard rules of multiplication of representations of the permutation group. In this simple case, the operators we construct will be equivalent to the naive product of operators corresponding to a maximal size D-brane (a determinant) and any other D-brane (sub-determinant). Extending this interpretation, we propose:

> *Given a collection of $\frac{1}{2}$-BPS D-branes and the related Young diagram with m boxes, a state with k open strings is created by the Young operator $\mathcal{O}_{Young}$ associated to the tableau made by filling k boxes in arbitrary locations with open string defects and $m-k$ boxes with a complex scalar Φ.*

Excitations of other members of a 1/2 BPS multiplet are constructed by acting on the Young tableau and operator with the broken SUSY generators. To test our proposal we will answer the following questions: (1) How many independent k string states can we construct? Do these states and their number satisfy the restrictions imposed by Gauss' law on the D-branes? (2) Are these operators approximately orthogonal at large N?

It is useful to start with a simple example. Consider the Young diagrams in Fig. 3 and construct operators by replacing $1, 2 \to \Phi$ and $3 \to Y$. (We only list three of the six Young tableaux and one of the three possible substitutions by Φ and Y because the other choices give identical operators.) These states are not heavy enough to be excited D-branes, but they will be instructive nevertheless. Alternatively we

---

[6] Of course if $\Phi_i \in SU(N)$, traces of a single matrix will vanish.

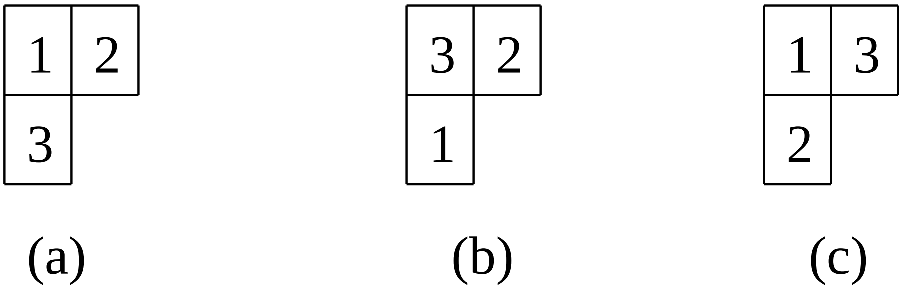

Figure 3: The three possible Young tableau of S_3 that give different operators under the replacement $1, 2 \to \Phi$ and $3 \to Y$.

could imagine that both columns have $m \sim N$ boxes above them which have been suppressed for simplicity – we could then think of this physically as two giant gravitons with an open string attached to them. The three Young operators are

$$\begin{aligned}
Y_a &= (\mathrm{Tr}\,\Phi)^2\,\mathrm{Tr}\,Y - \mathrm{Tr}\,\Phi\,\mathrm{Tr}\,\Phi Y + \mathrm{Tr}\,\Phi^2\,\mathrm{Tr}\,Y - \mathrm{Tr}\,\Phi^2 Y \\
Y_b &= (\mathrm{Tr}\,\Phi)^2\,\mathrm{Tr}\,Y - \mathrm{Tr}\,\Phi^2 Y \\
Y_c &= (\mathrm{Tr}\,\Phi)^2\,\mathrm{Tr}\,Y - \mathrm{Tr}\,\Phi^2\,\mathrm{Tr}\,Y + \mathrm{Tr}\,\Phi\,\mathrm{Tr}\,\Phi Y - \mathrm{Tr}\,\Phi^2 Y
\end{aligned}$$

and there is one relation among them

$$2Y_b = Y_a + Y_c$$

Thus there are two independent states, which we can take to be created by the tableaux in Fig. 3a and 3c. This is consistent with Gauss' Law for compact D-branes. A single string starting on a compact brane must also end on it so that the flux produced by the endpoint has both a source and a sink. By contrast there are four oriented string states on and between two noncompact D-branes. A direct enumeration of Young operators and their relationships is intractable in the general case, so in what follows we will approach the problem of finding independent excited D-brane states more abstractly.

Before ending the introduction of this section, we would like to give a remark about the formula (44), where upper indices are fixed and permutations act only on lower indices. This approach used only one Young diagram of lower indices and is different from the two Young diagram method given in section 5.1. However, it can be shown that these two methods are equivalent to each other. The reason is the following. The sum $\sum_{s\in up}\sum_{t\in down}\Phi^{I_{s(i)}}_{I_{t(i)}}$ can be rewritten as $\sum_{s\in up}\sum_{t\in down}\Phi^{I_i}_{I_{ts^{-1}(i)}}$. Summing over all s, t is equivalent to acting with $c_d \cdot c_u$ on lower indices like (44) where c_u and c_d are corresponding Young elements (43). There are some basic mathematical facts regarding Young elements that can be found in [30]. First, if the upper Young tableau and lower Young tableau belong to different Young diagrams then

$c_d \cdot c_u = 0$. This explains the intuitive picture that both upper and lower index Young diagrams must have same shape to get nonzero results. Second, for the upper and lower Young tableaux of same Young diagram, the product can be expanded into the linear combination of Young elements, i.e.,

$$c_d^\alpha \cdot c_u^\alpha = \sum_{i \in \alpha} f_i c_i^\alpha$$

where we use explicitly α to denote a given Young diagram. Since formula (44) has included all permutations c_i^α, operators given by the two Young diagram method of section 5.1 will just be linear combinations of those with the one Young diagram method used in this section.

5.2.1 A formulation of the problem of counting strings

Consider again a single string attached to a system of two D-branes. The Young diagram consists of two columns with $n = n_1 + n_2$ boxes and there are $n!$ ways to label the boxes with numbers $1 \cdots n$ to get a Young tableau. To construct the relevant Young operators we can replace $1, 2, ..., (n-1) \to X$ and $n \to Y$. (Making any other choice of replacement of labels will lead to the same set of operators.) The resulting set of operators will be invariant under permutations of the labels $1 \cdots (n-1)$ by $S_{n-1} \in S_n$. Now recall that each assignment of labels $1 \cdots n$ to a tableau is associated to a specific Young element of the group algebra (43) which is not in general invariant by itself under S_{n-1}. Therefore finding an independent basis of operators with two branes and one open string excitation is equivalent to finding a basis for the S_{n-1} invariant subalgebra within the algebra generated by the Young elements Y_i (i.e., $\sigma(\sum_i a_i Y_i)\sigma^{-1} = \sum_i a_i Y_i$ for $\forall \sigma \in S_{n-1}$). This prescription is easily generalized. For example, if the excitation involves two open string states Y_1, Y_2 with $Y_1 \neq Y_2$ we must enumerate S_n group algebra elements that are invariant under S_{n-2}, but if $Y_1 = Y_2$, we seek group algebra elements under $S_{n-2} \times S_2$.

This splitting might seem artificial at first sight. However, when we compute correlators in two point functions, in the end we sum over all permutations of *identical* objects, which is just the statement that we compute these using Wicks theorem. This will give us sums over subgroups of S_n that permute the matrices which are to be treated as identical, but will not sum over permutations that exchange different matrices: these do not appear in the free field contractions.

5.2.2 Counting the open string states

We have reduced the problem of counting the number of k string states on a collection of D-branes to enumerating elements of the S_n group algebra that are invariant under subgroups of S_n. Our task is aided by the following facts about the permutation group [30]:

- (1) A given Young diagram is associated to a single irreducible representation of S_n with dimension d (which can be determined from the diagram) and unitary representation matrix $D^R_{ij}(s)$ for $s \in S_n$. There are *orthogonality relationships* among these unitary matrices:

  $$\sum_{s\in G} D^{(\mu)}(s)_{il}\overline{D^{(\nu)}(s)_{sm}} = \frac{N_G}{d_\mu}\delta_{is}\delta_{lm}\delta_{\mu\nu}\,. \tag{45}$$

  The overline denotes complex conjugation, N_G is the dimension of the group G and d_μ is the dimension of the irreducible representation μ.

- (2) The $n!$ ways of labeling the n boxes of a Young diagram to give a Young tableau are associated with $n!$ Young elements of the S_n group as in (43). If the diagram is related to a S_n representation of dimensions d, there are d^2 linearly independent Young elements. A basis for them is:

  $$A^R_{ij} = \sum_{s\in S_n} \overline{D}^R_{ij}(s)\cdot s \tag{46}$$

  It is easily checked that

  $$g\cdot A^R_{ij}\cdot g^{-1} = \overline{D^R(g^{-1})}_{ik}A^R_{kl}\overline{D^R(g)}_{lj} = A^R_{kl}D^R(g)_{ki}\overline{D^R(g)}_{lj} \tag{47}$$

- (3) Under the decomposition $S_{n_1+n_2} \to S_{n_1}\times S_{n_2}$, the representation R of $S_{n_1+n_2}$ decomposes as

  $$R|_{S_{n_1+n_2}} = \sum_{R_1,R_2} C^R_{R_1,R_2} R_1|_{S_{n_1}} \times R_2|_{S_{n_2}} \tag{48}$$

  where the Littlewood-Richardon coefficients $C^R_{R_1,R_2}$ count the multiplicity of each product representation within R. By Frobenius Reciprocity, $C^R_{R_1,R_2}$ equivalently counts the number of times R appears in the product of R_1 and R_2 (i.e., $R_1 \times R_2 \uparrow^{S_{n_1+n_2}}$) [30]. The latter can be calculated easily by the Littlewood-Richardson rule for multiplying Young tableaux (see, e.g., Appendix A of [31]).[7] Examples of carrying out this procedure for tableaux with two columns are given in Fig. 4 ($S_n \to S_{n-1}$), Fig. 5 ($S_n \to S_{n-2}$) and Fig. 6 ($S_n \to S_{n-1}\times S_2$).

With these preparations we can calculate the number of independent operators. First, note that (47) simply expresses the fact that A^R_{ij} transforms as a tensor product

---

[7] The Littlewood-Richardson rule for multiplying Young diagrams $R_1 \otimes R_2$ is as follows. Label each box of the ith row of R_2 by i. Attach the boxes of of R_2 to R_1 in any way that gives a valid Young diagram, while obeying two constraints: (1) No boxes with the same number in them can appear in the same column, (2) Reading from right to left and starting with the top row and working down, the number of times the integer i appears must be no less than the number of times the integer $i+1$ appears.[31] The Littlewood-Richardson coefficients count the number of times a particular Young diagram appears in this procedure.

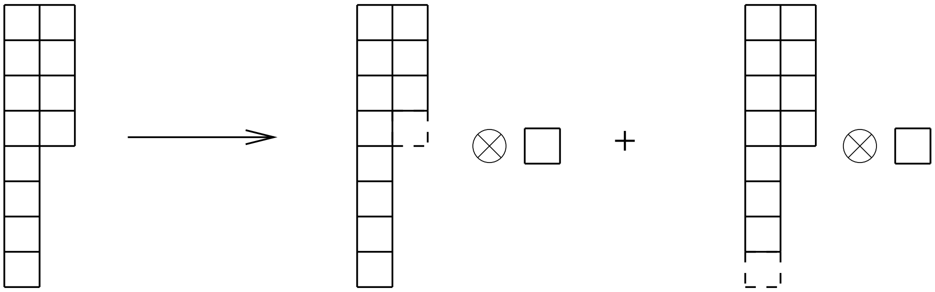

Figure 4: The decompsition of S_n to $S_{n-1} \times S_1$. The dashed boxes indicate where the single box of S_1 can attach (see footnote 7).

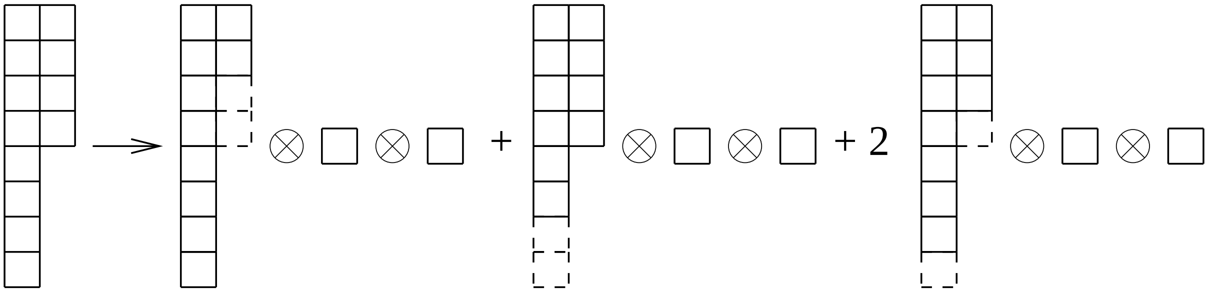

Figure 5: The decomposion of $S_n \to S_{n-2} \times S_1 \times S_1$. The dashed boxes indicate where the single boxes of the two S_1s can attach. The factor of 2 indicates that the third S_{n-2} diagram appears twice via the Littlewood-Richardson multiplication rules (see footnote 7).

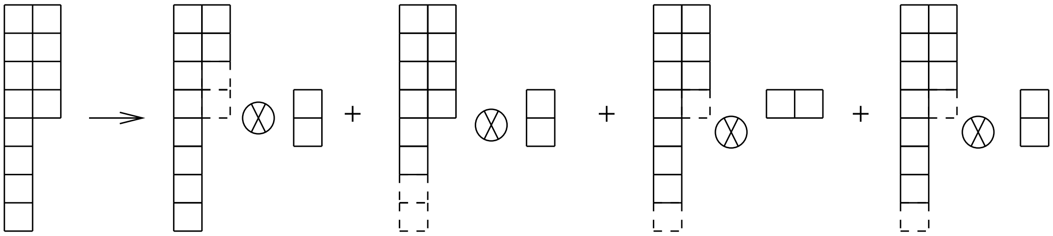

Figure 6: The decomposition of $S_n \to S_{n-2} \times S_2$. The dashed boxes indicate where the boxes of the S_2 diagram can attach (see footnote 7).

of D^R and $\overline{D^R}$. To see this, assume vector space V with basis $e_1, ..., e_l$ carries the representation R and that a vector space W with basis $\eta_1, ..., \eta_k$ carries the representation S. The tensor space $V \otimes W$ with basis $e_i \otimes \eta_\alpha$ satisfies

$$\begin{aligned} g(e_i \otimes \eta_\alpha) &= (ge_i) \otimes (g\eta_\alpha) = \left(e_j D^R(g)_{ji}\right) \otimes \left(\eta_\beta D^S(g)_{\beta\alpha}\right) \\ &= (e_j \otimes \eta_\beta) D^R(g)_{ji} D^S(g)_{\beta\alpha} \end{aligned} \tag{49}$$

Comparing (47) and (49) we reach our conclusion.

This reduces the problem of finding $G \subset S_n$ invariant operators to *counting the trivial representations of* G *inside the tensor product of* R *and* $\overline{R}$. This is easy to do. The group character χ has a decomposition

$$\chi^R|_G = \sum_k p_k \chi^k$$

where R is an irreducible representation of S_n, k is an irreducible representation of G decomposed from R and p_k is the number of times the representation k appears in the decomposition. Then

$$\chi^{\overline{R}} = \sum_k p_k \chi^{k*}$$

and finally

$$\begin{aligned} \dim &= \left\langle 1, \chi(R)\chi(\overline{R})\right\rangle = \sum_{i,j} p_i p_j \left\langle 1, \chi^i \chi^{j*}\right\rangle \\ &= \sum_{i,j} p_i p_j \left\langle \chi^j, \chi^i\right\rangle = \sum_k p_k^2 \end{aligned} \tag{50}$$

5.2.3 Examples: Gauss' Law recovered

We will demonstrate how our general result (50) manifests the constraints of Gauss' Law by considering several examples.

1. No open string excitations: If no strings are attached to a 1/2-BPS state of D-branes, we find the operator by replacing $1, 2, ..., n \to X$ in the n boxes of a tableau. The number of independent states thus equal the number of S_n invariant Young elements. Since each Young diagram corresponds to a single irreducible representation, there is unique S_n singlet Young element, and corresponding D-brane state. This is the result of [7].

2. One string attached to two different D-branes: This operator is computed by replacing $1, 2, ..., (n-1) \to X$ and $n \to Y$ in a Young diagram with two columns of different lengths. Fig. 4 showed that the corresponding S_n representation decomposes into a sum of two irreducible $S_{n-1} \times S_1$ representations each with multiplicity 1. Thus (50) shows that there are two independent operators. This matches Gauss' law: a single string starting on a spherical brane must also end on it, and therefore the two branes should give rise to two independent states. In particular, Gauss' law prohibits an open string connecting the two branes.

3. One string attached to two identical D-branes: In this case, Gauss' law and the equivalence of the two D-branes together imply that there is only one gauge invariant open string state. Indeed, for this special case the S_n representation with two equal columns decomposes into a single S_{n-1} irreducible representation in which the second column has one less box. Thus there is only one independent state, as expected.

4. Two distinct open strings attached to two different D-branes: We construct the operator by replacing $1, 2, ..., (n-2) \to X$, $(n-1) \to Y_1$ and $n \to Y_2$ in Young diagram of S_n with two unequal columns. Fig. 5 shows that the S_n diagram decomposes into a sum of three irreducible $S_{n-2} \times S_1 \times S_1$ representations. According to (50) this leads to $1^2 + 1^2 + 2^2 = 6$ independent states. This matches the Gauss law constrained number of states of two distinguishable strings on two distinguishable branes A and B: both strings on brane A or B (2 states), one string on A and the other on B (2 states), one oriented string stretched from A to B and vice versa (2 states).

5. Two distinct open strings attached to two identical D-branes: We construct the operator by replacing $1, 2, ..., (n-2) \to X$, $(n-1) \to Y_1$ and $n \to Y_2$ in a Young diagram of S_n with two equal columns. It is easily seen that in this case the S_n diagram decomposes into a sum of two irreducibles of $S_{n-2} \times S_1 \times S_1$, each with multiplicity 1. This implies two independent states. Naively one might have expected three independent states: (i) both strings on a single brane, (ii) one string on each brane, and (iii) both strings stretched between the branes. However, since the the branes are identical the third state is gauge equivalent to the second so there should be only two independent states.

6. Two identical open strings attached to two different D-branes: We construct the operator by replacing $1, 2, ..., (n-2) \to X$, $(n-1) \to Y_1$ and $n \to Y_1$ in a Young diagram of S_n with two unequal columns. As seen in Fig. 6, the S_n diagram decomposes into a sum of four irreducibles of $S_{n-2} \times S_2$, each with multiplicity 1. This leads by (50) to four independent states. The expected counting agrees: (a) both strings on a single brane (2 states), (b) one string on each brane (1 state), and (c) both strings stretched between the branes (1 state).

7. Two identical open strings attached to two identical D-branes: We construct the operator by replacing $1, 2, ..., (n-2) \to X$, $(n-1) \to Y_1$ and $n \to Y_1$ in a Young diagram of S_n with two equal columns. Unlike Fig. 6, since the two columns of the S_n diagram are equal length, it can be shown that the decomposition into $S_{n-2} \times S_2$ only leads to two irreducible diagrams. (In effect only the first and third products of Fig. 6 survive.) Thus there are two independent states. This is as expected from the discussion in example 5: all states are gauge equivalent to either two strings on the same brane, or on different branes.

Our proposal for constructing operators describing open string states on D-branes exactly reproduces the expected constraints imposed by Gauss' law. Remarkably, the combinatorics of Young diagrams even "knows" about the distinctions between identical and distinguishable brane and string states. This is strong evidence in favor of our identification between Young diagram operators and open string states on a system of D-branes. Although all the examples we have given involve two column Young diagrams, our proposal can be applied in general, for example, to n-column or n-row diagrams. In other words, our proposal describes the excited states of a general system of D-branes some of which might be extended into AdS_5 or into S^5 in the string theory description.

5.3 Constructing Young operators

In practical calculations one needs a convenient way of writing down the operators described in the previous section. Of course, we could always return to the definition (44) but this expression is unwieldy to compute. Below we develop two other techniques for constructing the operator

Projection operator method: Recall again that the Young diagram associated to a system of D-branes is also related to an irreducible representation R of S_n where n is the number of boxes in the diagram. As we have seen, identifying the open string operators on the D-branes requires extracting the trivial representations of some $G \in S_n$ within the tensor product $R \otimes \overline{R}$. A standard way of doing this is by constructing the appropriate projection operator. For the trivial representation the projection operator is

$$P_I = \frac{1}{n_G} \sum_{g \in G} T(g) \tag{51}$$

where $T(g)$ is the action of g in the represention $R \otimes \overline{R}$ and n_G is the number of elements in G. Using this, the action of the projection operator on the Young basis elements (46) is

$$\begin{aligned}
P_I \cdot A_{ij} &= \frac{1}{n_G}\sum_{g\in G} T(g)\cdot A_{ij} \\
&= \frac{1}{n_G}\sum_{g\in G}\sum_{k,l} A_{kl} D(g)_{ki}\overline{D(g)_{lj}} \\
&= \frac{1}{n_G}\sum_{g\in G}\sum_{k,l}\sum_{s\in S_n} \overline{D_{kl}(s)} D(g)_{ki}\overline{D(g)_{lj}}\cdot s
\end{aligned}$$

where we used (47) and then (46). To go further and simplify the calculation, we can choose a basis so that the representation R of S_n has block diagonal form when it is restricted to $G \subset S_n$. It is convenient to split the index k of the S_n representation R to reflect the decomposition into representations of G. Each such representation of G, which we label μ, could appear several times in R, so we will introduce α_μ to distinguish the multiple appearances. Then we write $k = [\mu, \alpha_\mu, t]$ where in addition to μ and α_μ we have included $t = 1 \cdots \dim(\mu)$. Likewise we split $i = [\tilde{\mu}, \tilde{\alpha}_\mu, \tilde{t}]$ and $i = [\tilde{\nu}, \tilde{\alpha}_\nu, \tilde{d}]$. With this notation,

$$\begin{aligned}
&\sum_{g\in G}\sum_{k,l} D(g)_{ki}\overline{D(g)_{lj} D_{kl}(s)} \\
=\;& \sum_{g\in G}\sum_{\mu,\nu}\sum_{\alpha_\mu,a_\nu}\sum_{t,d} D^{\mu,a_\mu;\widetilde{\mu},\widetilde{a}_\mu}(g)_{t\widetilde{t}}\overline{D^{\nu,a_\nu;\widetilde{\nu},\widetilde{\alpha}_\nu}(g)_{d\widetilde{d}}}\;\;\overline{D(s)_{[\mu,\alpha_\mu,t][\nu,\alpha_\nu,d]}} \\
=\;& \sum_{\mu,\nu}\sum_{\alpha_\mu,a_\nu}\sum_{t,d}\frac{n_G}{n_\mu}\delta_{\mu\widetilde{\mu}}\delta_{\nu\widetilde{\nu}}\delta_{\alpha_\mu\widetilde{\alpha}_\mu}\delta_{\alpha_\nu\widetilde{\alpha}_\nu}\delta_{\mu\nu}\delta_{td}\delta_{\widetilde{t}\widetilde{d}}\;\;\overline{D(s)_{[\mu,\alpha_\mu,t][\nu,\alpha_\nu,d]}} \\
=\;& \frac{n_G}{n_{\widetilde{\mu}}}\delta_{\widetilde{\mu}\widetilde{\nu}}\delta_{\widetilde{t}\widetilde{d}}\sum_t \overline{D(s)_{[\widetilde{\mu},\widetilde{\alpha}_\mu,t][\widetilde{\nu},\widetilde{\alpha}_\nu,t]}}
\end{aligned}$$

where in the third line we have used the block diagonal form of $D(g)$ and the corresponding orthogonality relationship (45) for G. Assembling everything we have

$$P_I \cdot A_{ij} = \sum_{s\in S_n}\frac{1}{n_{\widetilde{\mu}}}\delta_{\widetilde{\mu}\widetilde{\nu}}\delta_{\widetilde{t}\widetilde{d}}\sum_t \overline{D(s)_{[\widetilde{\mu},\widetilde{\alpha}_\mu,t][\widetilde{\nu},\widetilde{\alpha}_\nu,t]}}\cdot s \qquad (52)$$

Nonzero contributions to this projection require $\widetilde{\mu} = \widetilde{\nu}$ and $\widetilde{t} = \widetilde{d}$, but $\widetilde{\alpha}_\mu, \widetilde{\alpha}_\nu$ can be arbitrary. In other words, the identity representation is extracted from the tensor products of any of the multiple occurrences of each representation μ of G in the decomposition of R with their conjugates.

The expression (52) is a weighted sum of permutations. Applying it to a sequence $\Phi_1 \cdots \Phi_n$ of unitary matrices as in (44) we get the desired operator.[8] We use this expression in Sec. 5.4 and the appendices to show orthogonality for 1-string states on arbitrary D-brane states.

---

[8] By this we mean that the weighted sum of permutations of lower indices in (44) should be replaced by the weighted sum of permutations in (52).

Matrix method: In fact, (52) can be understood directly from matrix algebra. For example, suppose $R \to R_1 + 2R_2$ under the decomposition $S_n \to G$. We can choose a basis for R so that

$$D^R(g) = \begin{bmatrix} D^{R_1} & 0 & 0 \\ 0 & D^{R_2} & 0 \\ 0 & 0 & D^{R_2} \end{bmatrix}, \qquad \forall g \in G$$

Then using the middle form of (47) we have

$$\begin{aligned} A_{ij} \quad &\to \begin{bmatrix} \overline{D^{R_1}}^{-1} & 0 & 0 \\ 0 & \overline{D^{R_2}}^{-1} & 0 \\ 0 & 0 & \overline{D^{R_2}}^{-1} \end{bmatrix} \cdot A_{ij} \cdot \begin{bmatrix} \overline{D^{R_1}} & 0 & 0 \\ 0 & \overline{D^{R_2}} & 0 \\ 0 & 0 & \overline{D^{R_2}} \end{bmatrix} \\ &= \begin{bmatrix} \overline{D^{R_1}}^{-1} A_{11} \overline{D^{R_1}} & \overline{D^{R_1}}^{-1} A_{12} \overline{D^{R_2}} & \overline{D^{R_1}}^{-1} A_{13} \overline{D^{R_2}} \\ \overline{D^{R_2}}^{-1} A_{21} \overline{D^{R_1}} & \overline{D^{R_2}}^{-1} A_{22} \overline{D^{R_2}} & \overline{D^{R_2}}^{-1} A_{23} \overline{D^{R_2}} \\ \overline{D^{R_2}}^{-1} A_{31} \overline{D^{R_1}} & \overline{D^{R_2}}^{-1} A_{32} \overline{D^{R_2}} & \overline{D^{R_2}}^{-1} A_{33} \overline{D^{R_2}} \end{bmatrix} \end{aligned}$$

where we introduced block indices $1, 2, 3$. Then it is evident that traces of some of the blocks, namely $\mathrm{Tr}\, A_{11}$, $\mathrm{Tr}\, A_{22}$, $\mathrm{Tr}\, A_{23}$, $\mathrm{Tr}\, A_{32}$ and $\mathrm{Tr}\, A_{33}$, provide a basis of G-invariant group algebra elements. This is simply an explicit realization of (52) that can be used to construct gauge-invariant Yang-Mills operators as described in footnote (8).

It is useful to illustrate these methods with a couple of examples. First consider a general 1/2-BPS state. Then using (46), the S_n invariant element of the group algebra is $\mathcal{O} = \sum_{i=1}^{d} A_{ii} = \sum_{s \in S_n} \chi^R(s) s$. (Here we have used the property $\chi(s) = \chi^*(s)$ because all irreducible representations of S_n have real characters.) This reproduces the Schur polynomical form given in [7], and the corresponding gauge invariant operator can be constructed as described above. Second, consider a system of two distinct D-branes and an open string. Then the representation R of S_n decomposes to a sum $R_1 + R_2$ of S_{n-1} as described in the examples in the previous section. The two associated S_{n-1} invariant group algebra elements are

$$\mathcal{O}_{R,R_1} = \sum_{s \in S_n} \sum_{i=1}^{d_{R_1}} \overline{D}^R_{ii}(s) s \tag{53}$$

$$\mathcal{O}_{R,R_2} = \sum_{s \in S_n} \sum_{i=d_{R_1}+1}^{d_R} \overline{D}^R_{ii}(s) s \tag{54}$$

where we have chosen $D^R(g \in S_{n-1})$ to be block diagonal. It is not clear how to simplify (53) and (54) further. While for $g \in G$, the block trace in these operators is simply the charcater of R_1 and R_2, for $g \in S_n, g \notin G$ there is no obvious clean interpretation. It would be nice to have a more powerful technique for evaluating these traces.

5.4 Tree level orthogonality of Young operators

The combinatorial emergence of Gauss's law from our Young diagrams is strong evidence that we have correctly identified the operators describing strings on D-branes from the Yang-Mills perspective. However, it would also be nice to prove that we have a good orthogonal basis, at least at tree level and in the large N limit. The challenge here is that we do not have a general expression for the block traces the previous section, and a case by case enumeration of the multi-string operators is not tractable. However, we have been able to show that the various operators describing single strings attached to a multi-brane system are indeed orthogonal. This amounts to showing that the matrix of 2-point functions of these operators is diagonal. The general calculation is lengthy and is presented in Appendix C. The result is

$$\left\langle \mathcal{O}^{\dagger}_{R,R_1} \mathcal{O}_{S,S_1} \right\rangle \sim 0, \quad R \neq S \;\; or \;\; R_1 \neq S_1 \tag{55}$$

in large N limit. Here R, S are S_n representations that determine the system of branes and R_1, S_1 are S_{n-1} representations that determine the open string state. This shows that at least arbitrary combinations of 1/2-BPS D-branes with one string on them, our proposal provides a good orthogonal basis of operators.

6 Dynamical emergence of non-Abelian structure

In the previous section we took the first step towards demonstrating the appearance of a new gauge symmetry by showing how Gauss' law emerges from the combinatorics of Young diagrams. In this section we will provide evidence that the emergent symmetry will be non-Abelian in the presence of multiple branes by showing how perturbative loops sense the rank of the group. From the perspective of string theory we will show that the Chan-Paton factors associated with strings in a multi-brane system dynamically emerge from Yang-Mills theory. Our basic tactic is to compute the one-loop anomalous dimension of operators representing a string attached to two branes. When the branes are identical we should expect a result that is twice the answer for a single brane because of the trace over the indices of the enhanced gauge group associated to coincident branes, or, equivalently, because open strings can end on multiple branes (see Fig. 8).

The operator expressions (52) are still too complicated for a general calculation. Hence we will consider a special case: an open string attached to a two D-brane system in which one brane is of maximal size. Gauss' law will forbid a string stretched between two such branes, so there should two states: a string attached to the small brane and a string attached to the big brane. The obvious guess for the corresponding

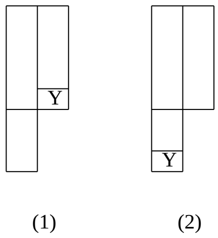

Figure 7: The two orthogonal Young diagrams representing a string (Y) attached to a pair of D-branes of different sizes

operators is

$$P_1 \equiv \epsilon^{i_1 i_2 \ldots i_N}_{j_1 j_2 \ldots j_N} \Phi^{j_1}_{i_1} \Phi^{j_2}_{i_2} \ldots \Phi^{j_N}_{i_N} \epsilon^{\tilde{i}_1 \tilde{i}_2 \ldots \tilde{i}_M \tilde{k}_1 \ldots \tilde{k}_{N-M}}_{\tilde{j}_1 \tilde{j}_2 \ldots \tilde{j}_M \tilde{k}_1 \ldots \tilde{k}_{N-M}} \Phi^{\tilde{j}_1}_{\tilde{i}_1} \Phi^{\tilde{j}_2}_{\tilde{i}_2} \ldots \Phi^{\tilde{j}_{M-1}}_{\tilde{i}_{M-1}} (Y^J)^{\tilde{j}_M}_{\tilde{i}_M} \tag{56}$$

$$P_2 \equiv \epsilon^{i_1 i_2 \ldots i_N}_{j_1 j_2 \ldots j_N} \Phi^{j_1}_{i_1} \Phi^{j_2}_{i_2} \ldots \Phi^{j_{N-1}}_{i_{N-1}} (Y^J)^{j_N}_{i_N} \epsilon^{\tilde{i}_1 \tilde{i}_2 \ldots \tilde{i}_M \tilde{k}_1 \ldots \tilde{k}_{N-M}}_{\tilde{j}_1 \tilde{j}_2 \ldots \tilde{j}_M \tilde{k}_1 \ldots \tilde{k}_{N-M}} \Phi^{\tilde{j}_1}_{\tilde{i}_1} \Phi^{\tilde{j}_2}_{\tilde{i}_2} \ldots \Phi^{\tilde{j}_M}_{\tilde{i}_M} \tag{57}$$

We could naively interpret (56) as the product of an operator describing a maximal size D-brane ($\det \Phi$) and an operator describing a smaller D-brane (subdetΦ) with a string (Y^J) attached to the latter. Similarly (57) is naively a product of operators describing a maximal brane with a string on it, and a smaller brane. However, as shown in Appendix B this naive guess is not quite correct – the two operators make states that are not orthogonal to each other. Rather, following the proposal in the previous section the two orthogonal one string states should be described by the Young diagrams in Fig. 7. The corresponding operators are:

$$\mathcal{O}_1 = \frac{(N+1)}{(N-M+1)} P_1 \tag{58}$$

$$\mathcal{O}_2 = \frac{N}{(N-M)} P_2 - \frac{M}{(N-M)(N-M+1)} P_1 \tag{59}$$

Following the calculations in Appendix B, $\mathcal{O}_1$ and $\mathcal{O}_2$ make orthogonal states at tree level. It is pleasant to note that when $M \ll N$ so that the two branes are very different in size, the naive guess is correct, i.e., $\mathcal{O}_i \approx P_i$.

How small should M be so that the branes are well separated? Recall on AdS$_5 \times S^5$ a single brane with R-charge M moves on a circle of radius

$$r = R \left(1 - \frac{M}{N} \right)^{1/2} , \tag{60}$$

where R is the AdS scale. The large brane (with $M = N$) is thus at the origin $r = 0$. In order for the branes to be separated by more than a string length we require

$$r > l_s \, . \tag{61}$$

Recalling that $R \sim l_s \lambda^{1/4}$ where λ is the 't Hooft coupling, and we are dropping factors 2π, this condition translates into

$$M < N \left(1 - \frac{1}{\sqrt{\lambda}} \right) \tag{62}$$

So we if we take $M = \alpha N$ for any $\alpha < 1 - 1/\sqrt{\lambda}$ the branes are separated by more than a string length at large 't Hooft coupling and the spectator brane should be largely irrelevant to the dynamics of a string on one of the branes. However, in the perturbative calculations below we work at small 't Hooft coupling for which this bound is very restrictive. When λ is very small, the scale of both AdS_5 and S^5 is the string length, so the branes are never much more than a string length apart.

Weak coupling results for BPS observables can be extrapolated to strong coupling where the S^5 is large and the supergravity analysis is valid, but the operators (58,59) are only near-BPS. Indeed, we will see leading order agreement with the supergravity expectations, but there will be small $O(1)$ differences. Indeed the fact that (62) contains a $\sqrt{\lambda}$ immediately tells us that a naive perturbative large N analysis in the Yang-Mills theory will not directly reproduce this bound.

To arrive at our results below we will be computing correlation functions of operators like P_1 and P_2. In these calculations, while the contractions between the Φs will be carried out exactly, those between the Ys are done at the planar level. In this sense our computations are at the leading order in large N. One loop corrections from interactions are also evaluated in the planar limit for contractions between Ys. The latter are suppressed by powers of the coupling, but not by powers of N.

6.1 Rank of the emergent gauge group

We will now show that as the two branes (58) and (59) coincide, the one-loop anomalous dimension of an open string becomes twice the answer for a single brane. This demonstrates the dynamical emergence of the Chan-Paton factors for open strings on coincident branes, or, equivalently, the enhancement of the low energy gauge theory to a non-Abelian group. The calculations are straightforward but lengthy. Hence we will not present the detailed steps,[9] but present the results directly. We will always assume that M is $O(N)$, so that the smaller object can be interpreted as a D-brane rather than as a closed string ($M \sim O(\sqrt{N})$) or as a supergravity mode ($M \sim O(1)$).

String on the large brane: The general expressions simplify when $(M - N)$ is $O(N)$ also. This condition is equivalent to setting

$$M = \alpha N \quad ; \quad 0 < \alpha < 1 \tag{63}$$

---

[9] Appendix D gives a flavor of the computations involved.

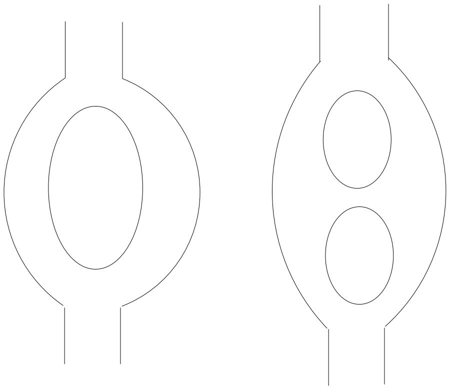

Figure 8: An one loop open string diagram and a two loop open string diagram. The inner lines (circles) represents the branes that open string can end on.

so that

$$\mathcal{O}_2 \propto P_2 \tag{64}$$

to leading order in N. The tree level and 1-loop two-point functions of P_2 turn out to be

$$\begin{aligned} \langle P_2(x)\bar{P}_2(0)\rangle_{\rm tree} &= \frac{N^{J-1}(N-M)!N!^4M!^2g_s^{N+M+J-1}}{(N-M+1)(2\pi|x|^2)^{N+M+J-1}} \equiv \frac{C_2}{|x|^{2\Delta}} & (65)\\ \langle P_2(x)\bar{P}_2(0)\rangle_{\rm 1-loop} &= -\frac{2g_s}{\pi}(J-1)(1+\frac{M}{N})\frac{C_2}{x^{2\Delta}}\log(|x|\Lambda) & (66)\end{aligned}$$

where $\Delta = N+M+J-1$ is the free field dimension of the operator. From this we read off the anomalous dimension

$$\delta\Delta_{\rm 1-loop,2} = \frac{g_s(J-1)}{\pi}(1+\frac{M}{N})\frac{g_s(J-1)}{\pi}(1+\alpha)\,. \tag{67}$$

When $\alpha \ll 1$, so that the spectator brane is far from the larger one, this approaches the the result for a string on a single maximal sized D-brane ($N = M$ in (38)). By contrast, when $\alpha \to 1$, so that the spectator brane approaches the larger one, we get twice the single brane answer. This exactly reproduces the expected effect of having multiple coincident branes in open string loop diagrams. One loop and two loop diagrams for open string propagation are depicted in Fig. 8. In the large N limit, such open string loops are identified with loop amplitudes in the gauge theory. At l loops there are l inner circles in Fig. 8, each of which can end on any of the branes present, enhancing the amplitude by G^l. Hence the factor of 2 in the one-loop contribution (67). At low energies, the dynamics of the string should then give rise to a non-Abelian gauge theory as $\alpha \to 1$.

String on the small brane: In this case we assume $M = O(N)$ and keep terms at leading order in M and N. The tree level and one loop two-point functions are:

$$\langle P_1(x)\bar{P}_1(0)\rangle_{\rm tree} = \frac{N^J\,(N-M)!\,N!^4\,M!\,(M-1)!\,g_s^{N+M+J-1}}{(N-M+2)(2\pi|x|^2)^{N+M+J-1}} \equiv \frac{C_1}{|x|^{2\Delta}} \tag{68}$$

$$\langle P_1(x)\bar{P}_1(0)\rangle_{\rm 1-loop} = -\frac{2g_s}{\pi}((N-M)+2J-1-\frac{1}{N-M+1})\frac{C_1}{x^{2\Delta}}\log(|x|\Lambda) \tag{69}$$

where Δ is the free field dimension of the operator. The anomalous dimension is therefore

$$\delta\Delta_{1-{\rm loop},1} = \frac{g_s}{\pi}((N-M)+2J-1-\frac{1}{N-M+1}) \tag{70}$$

As $M \to N$, like (67), this approaches twice the answer for a single maximal size brane, reproducing the expected enhancement due the presence of multiple branes. When $M \ll N$ the spectator maximal size brane is far from the brane and (70) agrees at leading order with the result for a string on a single brane ($M < N$ in (38)). At the next to leading order, there is a disagreement by a factor of 2 in front of J. It is expected that there will be some disagreement. We are extrapolating from very weak 't Hooft coupling where the separation is never more than a string length to strong coupling where the branes are well separated. Since we are not discussing BPS quantities, it is surprising that the agreement is so good at the subleading level. The near-BPS character of the operators is conferring some residual protection to the anomalous dimension.

Discussion: As $M \to N$, we should strictly speaking account for the the non-vanishing overlap between P_2 and P_1 by taking the orthogonal combinations (58,59). We have not done so because when $M = N$, in fact $P_2 = P_1$ and all overlaps give the same answer which will be twice the answer for a single brane as shown above. When $M \ll N$ we can likewise neglect the overlaps of P_2 and P_1 at the present order of analysis, but for intermediate values of M it is important to correctly account for the tree-level diagonalization of operators. In any case, our results clearly show the emergence of the Chan-Paton factors associated to multiple coincident branes. At low energy this should lead to a new non-Abelian gauge symmetry arising from the brane dynamics. As the branes separate (i.e., as M is changed), the Chan-Paton factors discretely interpolate between integers.

6.2 Emergent string interactions

In previous sections we established that: (1) open strings emerge from the dynamics of D-brane operators in Yang-Mills theory, (2) Gauss' law is realized on multi-brane systems, (3) the Chan-Paton factors of multiple branes appear dynamically, plausibly allowing the appearance of non-Abelian gauge theory on multiple coincident branes.

This is enhanced by the fact that we seem to get the correct counting of single string and two string states for the non-abelian theory.

The challenge now is to establish that the excitations of the D-branes have the detailed interactions of a (emergent) gauge theory. Here we take the first step by simply displaying the kinds of CFT calculations that should be related to the splitting and joining of open strings on D-branes.

6.2.1 Interactions of strings in their ground state

Let us study the basic interaction of string theory – the splitting of one string into two. The simplest situation to examine is one in which the open strings are in their ground states. Operators corresponding to D-branes with one and two string excitations are:

$$\begin{aligned} \mathcal{O}_1 &= \epsilon^{j_1\cdots j_M}_{i_1\cdots i_M} Z^{i_1}_{j_1}\cdots Z^{i_{M-1}}_{j_{M-1}}(Y^J)^{i_M}_{j_M} && (71)\\ \mathcal{O}_2 &= \epsilon^{j_1\cdots j_M j_{M+1}}_{i_1\cdots i_{M+1}} Z^{i_1}_{j_1}\cdots Z^{i_{M-1}}_{j_{M-1}}(Y^{J_1})^{i_M}_{j_M}(Y^{J_2})^{i_{M+1}}_{j_{M+1}} && (72)\end{aligned}$$

Here $Y=\frac{1}{\sqrt{2}}(\phi^3+i\phi^4)$ and the R-charge $J=J_1+J_2$ is large, but $1\ll J\ll M,N$. (We will typically take $J\sim\sqrt{N}$ leading to a string with well-controlled interactions of the kind studied in [18, 11].)[10] The two point function $\langle\mathcal{O}_1\overline{\mathcal{O}}_2\rangle$ will be related to the open string field theory vertex describing an open string on a giant graviton splitting into two open strings, as in the case of BMN operators in [32, 33]. Open string field theory in a context related to the present one was studied in [34].

For simplicity we only consider the free field correlator $\langle\mathcal{O}_1\overline{\mathcal{O}}_2\rangle$. We also omit the spacetime dependent factor $\frac{g_s}{2\pi|x|^2}$ to simplify notation. To leading order in N, the normalizations and interactions of our operators are

$$\begin{aligned} \langle\mathcal{O}_1\overline{\mathcal{O}}_1\rangle &= \frac{(M-1)!^2(M-1)(N-2)!N^{J+1}}{(N-M)!}\,, && (73)\\ \langle\mathcal{O}_2\overline{\mathcal{O}}_2\rangle &= \frac{(M-1)!^2(M-1)(M-2)(N-2)!N^{J}}{(N-M-1)!}\,, && (74)\\ \langle\mathcal{O}_1\overline{\mathcal{O}}_2\rangle &= -2\frac{(M-1)!^2(M-1)(N-2)!N^{J}}{(N-M-1)!}\,, && (75)\end{aligned}$$

leading to the normalized interaction amplitude [11]

$$\frac{\langle\mathcal{O}_1\overline{\mathcal{O}}_2\rangle}{\sqrt{\langle\mathcal{O}_1\overline{\mathcal{O}}_1\rangle\langle\mathcal{O}_2\overline{\mathcal{O}}_2\rangle}}=-2\sqrt{\frac{N-M}{(M-2)N}}\,. \qquad (76)$$

---

[10] Recall that a string with spacetime mass $E\sim 1/l_s$ has a CFT dimension $\Delta\sim R/l_s\sim N^{1/4}$ where R is the AdS scale, and a near BPS state should have R-charge $J\sim\Delta$.

[11] In computing $\langle\mathcal{O}_2\overline{\mathcal{O}}_2\rangle$ we have assumed $J_1\neq J_2$. $\langle\mathcal{O}_2\overline{\mathcal{O}}_2\rangle$ will have an extra factor of 2, if $J_1=J_2$.

Interestingly, the amplitude is independent of the R-charges. When both M and N are of $O(N)$, the amplitude is $O(1/\sqrt{N})$. This is suppressed at large N. This may seem surprising given that at large J we have a very heavy string state. In fact, such suppression of the decay amplitude of heavy rotating rotating open strings occurs even for D-branes in flat space [35]. (Similar results for closed strings are obtained in [36].) Nevertheless, if the R-charge J is large (say $O(\sqrt{N})$), the sum over partitions of J into J_1 and J_2 will lead to an unsupressed inclusive splitting amplitude. This is reminiscent of the closed string splitting amplitude described by BMN operators [32].

Closed string emission: We can also study amplitudes for closed string emission from an excited D-brane. The operator corresponding to a D-brane along with an emitted closed string is

$$\mathcal{O}_3 = \epsilon^{j_1 \cdots j_{M-1}}_{i_1 \cdots i_{M-1}} Z^{i_1}_{j_1} \cdots Z^{i_{M-1}}_{j_{M-1}} \mathrm{tr}(Y^J) \tag{77}$$

At leading order in N the two point functions are

$$\langle \mathcal{O}_3 \overline{\mathcal{O}}_3 \rangle = \frac{J(M-1)!^2 N! N^J}{(N-M+1)!} \quad ; \quad \langle \mathcal{O}_1 \overline{\mathcal{O}}_3 \rangle = \frac{J(M-1)!^2 (N-1)! N^J}{(N-M)!} \tag{78}$$

leading to the normalized interaction amplitude

$$\frac{\langle \mathcal{O}_1 \overline{\mathcal{O}}_3 \rangle}{\sqrt{\langle \mathcal{O}_1 \overline{\mathcal{O}}_1 \rangle \langle \mathcal{O}_3 \overline{\mathcal{O}}_3 \rangle}} = \sqrt{\frac{(N-M+1)J}{(M-1)N}} \tag{79}$$

The amplitude scales as $\sqrt{\frac{J}{N}}$, if M and N are of the same order.

6.2.2 Splitting and joining of excited string states

In Sec. 4 we showed that (14) and (15) are open string fluctuations that realize Neumann and Dirichlet boundary conditions respectively. We can consider the interactions of such excited string states. Following [18, 11], it is convenient to "Fourier transform" the operators (14,15) representing single oscillator excitations with Dirichlet or Neumann boundary conditions to get:

$$\begin{aligned} \mathcal{O}_1^{D,m} &= \epsilon^{j_1 \cdots j_M}_{i_1 \cdots i_M} Z^{i_1}_{j_1} \cdots Z^{i_{M-1}}_{j_{M-1}} \Big(\sum_{l=0}^{J} \sin(\frac{\pi m l}{J}) Y^l \phi^I Y^{J-l}\Big)^{i_M}_{j_M} & (80) \\ \mathcal{O}_1^{N,m} &= \epsilon^{j_1 \cdots j_M}_{i_1 \cdots i_M} Z^{i_1}_{j_1} \cdots Z^{i_{M-1}}_{j_{M-1}} \Big(\sum_{l=0}^{J} \cos(\frac{\pi m l}{J}) Y^l \phi^K Y^{J-l}\Big)^{i_M}_{j_M} & (81) \end{aligned}$$

Here D represents Dirichlet boundary conditions and $\phi^I = \phi^5, \phi^6$, while N represents Neumann boundary conditions with $\phi^K = \phi^1, \phi^2$ [11]. The worldsheet momentum m satisfies $0 \leq m < J$ for Neumann modes and $0 < m < J$ for Dirichlet modes.

Similarly, operators representing a brane with two strings, one of which is excited by an oscillator mode, are given by

$$\mathcal{O}_2^{D,m} = \epsilon_{i_1\cdots i_M i_{M+1}}^{j_1\cdots j_M j_{M+1}} Z_{j_1}^{i_1}\cdots Z_{j_{M-1}}^{i_{M-1}}(\sum_{l=0}^{J_1}\sin(\frac{\pi m l}{J})Y^l\phi^I Y^{J_1-l})_{j_M}^{i_M}(Y^{J_2})_{j_{M+1}}^{i_{M+1}} \quad (82)$$

$$\mathcal{O}_2^{N,m} = \epsilon_{i_1\cdots i_M i_{M+1}}^{j_1\cdots j_M j_{M+1}} Z_{j_1}^{i_1}\cdots Z_{j_{M-1}}^{i_{M-1}}(\sum_{l=0}^{J_1}\cos(\frac{\pi m l}{J})Y^l\phi^K Y^{J_1-l})_{j_M}^{i_M}(Y^{J_2})_{j_{M+1}}^{i_{M+1}} \quad (83)$$

Finally, the operator describing a brane and a closed string is

$$\mathcal{O}_3^0 = \epsilon_{i_1\cdots i_{M-1}}^{j_1\cdots j_{M-1}} Z_{j_1}^{i_1}\cdots Z_{j_{M-1}}^{i_{M-1}}\mathrm{tr}(\phi^I Y^J)\,. \quad (84)$$

Because of the level matching condition for closed strings, only a zero mode excitation is possible in (84) with a single insertion of ϕ into the string of Ys [18].

As in the previous subsection, we calculate the two point functions of these operators. We find that for string splitting $\langle\mathcal{O}_1^{D,m_1}\mathcal{O}_2^{D,m_2}\rangle$ or $\langle\mathcal{O}_1^{N,m_1}\mathcal{O}_2^{N,m_2}\rangle$, the result is ($J = J_1 + J_2$)

$$\frac{\langle\mathcal{O}_1^{N(D),m_1}\overline{\mathcal{O}}_2^{N(D),m_2}\rangle}{\sqrt{\langle\mathcal{O}_1^{N(D),m_1}\overline{\mathcal{O}}_1^{N(D),m_1}\rangle\langle\mathcal{O}_2^{N(D),m_2}\overline{\mathcal{O}}_2^{N(D),m_2}\rangle}} - 2\sqrt{\frac{N-M}{(M-2)N}}\,\frac{1}{\sqrt{J_1 J}}\,\cos(\frac{\pi m_1 J_2}{2J})$$
$$\times\ \Big\{\frac{\sin(\frac{(J_1+1)\pi}{2}(\frac{m_1}{J}-\frac{m_2}{J_1}))}{\sin(\frac{\pi}{2}(\frac{m_1}{J}-\frac{m_2}{J_1}))}\cos(\frac{\pi m_1 J_2}{2J}+\frac{\pi J_1}{2}(\frac{m_1}{J}-\frac{m_2}{J_1}))$$
$$\pm\frac{\sin(\frac{(J_1+1)\pi}{2}(\frac{m_1}{J}+\frac{m_2}{J_1}))}{\sin(\frac{\pi}{2}(\frac{m_1}{J}+\frac{m_2}{J_1}))}\cos(\frac{\pi m_1 J_2}{2J}+\frac{\pi J_1}{2}(\frac{m_1}{J}+\frac{m_2}{J_1}))\Big\} \quad (85)$$

Here we assume that J_1 and J are both large and of the same order. The amplitude is suppressed relative to the ground state splitting computed in (76) unless $\frac{m_1}{J}\pm\frac{m_2}{J_1}\sim\frac{1}{J}$ or $\frac{m_1}{J}-\frac{m_2}{J_1}\sim\frac{1}{J}$ in which case one or both of the terms within the braces will be large enough to compensate for the overall $1/\sqrt{J_1 J}$. Notes that all these conditions imply $\frac{m_1}{J}-\frac{m_2}{J_1}\sim\frac{1}{J}$ since $0\le\frac{m_1}{J},\frac{m_2}{J_1}<1$. The condition $\frac{m_1}{J}=\frac{m_2}{J_1}$ should be understood as light cone momentum conservation, and is analogous to the level matching conditions in closed string case. For closed string emission, only the zero mode with Neumann boundary conditions contributes. The result remains the same as (79):

$$\frac{\langle\mathcal{O}_1^{N,0}\overline{\mathcal{O}}_3^0\rangle}{\sqrt{\langle\mathcal{O}_1^{N,0}\overline{\mathcal{O}}_1^{N,0}\rangle\langle\mathcal{O}_3^0\overline{\mathcal{O}}_3^0\rangle}}\sqrt{\frac{(N-M+1)J}{(M-1)N}} \quad (86)$$

7 Conclusion

In this paper we have accumulated evidence, building on previous works, that certain 1/2-BPS operators of $\mathcal{N}=4$ Yang-Mills theory are D-branes: (1) Their string-like excitations have Neumann and Dirichlet boundary conditions in appropriate directions,

(2) Multi-brane states beautifully realize Gauss' Law for strings ending on them via the combinatorics of associated Young diagrams, (3) The Chan-Paton factors associated with multiple coincident branes emerge dynamically. We have to temper our optimism of the prescription we have given, because there are some details of the description of strings stretching between D-branes that we were not able to do systematically. We have given a list of operators which we claim is a complete solution to the problem of stretching strings between giant gravitons, but we were not able to prove in general that the states corresponding to different configurations are orthogonal. Since we have given the list of operators, it is in principle possible to determine if our prescription is complete or not. We are currently looking into this issue. We also proposed a second basis for which we could do calculations systematically and we gave an implicit argument that they are equivalent. This was not at a level where we can translate between the two prescriptions by some sort of Fourier transform. We believe this issue should be explored further.

In Sec. 6 we also showed in this second basis how to compute CFT correlators associated with the interactions of strings on D-branes. It will be interesting to properly identify the dictionary relating these computations (e.g., (76) and (79)) to the string field theory on D-branes in $\mathrm{AdS}_5 \times S^5$. It is particularly intriguing that the low-energy dynamics of the branes should be described by an emergent gauge theory which is local, not on the S^3 on which the original Yang-Mills is defined, but rather on a new $3+1$ dimensional space which appears from the matrix degrees of freedom in the Yang-Mills theory. The emergent locality will involve an exchange between the $SO(4)$ rotation group of the original S^3 and the $SO(4)$ subgroup of the R-symmetry group that survives the introduction of a 1/2-BPS D-brane operator. Evidence from black hole dynamics led [37] to propose that in the presence of very heavy D-brane states the low-energy dynamics of a Yang-Mills theory should enjoy a duality with an emergent field theory which is local on a different space and can have different gauge and global symmetries.[12] The present paper establishes basic ingredients needed for showing how such a duality can arise.

It is worth mentioning that there is a considerable literature on how locality in the *bulk* of $\mathrm{AdS}_5 \times S^5$ (as opposed to on a D-brane) arises from the CFT point of view (e.g., [40, 41, 42, 43, 12]). In some cases like [44], knowing were interactions happen helps to resolve issues between 'field theory' behavior and 'string theory' behavior in scattering amplitudes. Perhaps even more important than understanding how locality appears, is a detailed description of how it breaks down. This is expected to give us some clue as to what happens at the Planck scale in a theory of quantum gravity, and perhaps will lead to a mathematically rigorous definition of the 'holographic principle', as opposed to the 'holographic behavior' that we can recognize in the AdS/CFT correspondence.

---

[12] It was also suggested in [37] that the new gauge group could have a higher rank than the Yang-Mills theory we start with. At least at the BPS level this looks problematic in view of the new class of supergravity solutions that has appeared in [9]. However, away from the BPS limit it may yet be possible for a lower rank gauge theory to have dynamics that is effectively described by a higher rank gauge theory. Indeed, the evidence for this from black hole entropy in [37] was in a non-BPS setting. See also the recent discussion [38, 39] about how to count the entropy of these states

Acknowledgments We thank Oleg Lunin for collaboration in the early stages of this work, and Asad Naqvi, Aki Hashimoto for many useful discussions about this material. M-x.H. thanks the second Simons workshop in mathematics and physics at Stony Brook for hospitality during part of the works.

A Some combinatorial properties

In this appendix we list some properties of the epsilon tensor that are useful for our calculations. The epsilon tensor is defined as

$$\epsilon^{i_1\cdots i_p}_{j_1\cdots j_p} = \begin{cases} 1 & \text{if } (i_1\cdots i_p) \text{ is an even permutation of } (j_1\cdots j_p)\ ; \\ -1 & \text{if } (i_1\cdots i_p) \text{ is an odd permutation of } (j_1\cdots j_p)\ ; \\ 0 & \text{otherwise.} \end{cases} \tag{87}$$

We work with $SU(N)$ gauge groups, so $p \leq N$ and both $i_1, \cdots, i_p$ and $j_1, \cdots, j_p$ are integers from 1 to N. As special cases we write:

$$\epsilon^{i_1\cdots i_N} = \epsilon^{i_1\cdots i_N}_{1\cdots N}\,, \tag{88}$$

$$\epsilon^{i_1\cdots i_N}\epsilon_{j_1\cdots j_N} = \epsilon^{i_1\cdots i_N}_{j_1\cdots j_N}, \tag{89}$$

$$\delta^i_j = \epsilon^i_j \tag{90}$$

Some properties of the epsilon tensor that are useful in computations of correlation functions of determinant and sub-determinant operators are:

$$\epsilon^{i_1\cdots i_p}_{j_1\cdots j_p} = \sum_{x=1}^{p}(-1)^{x+1}\delta^{i_1}_{j_x}\epsilon^{i_2\cdots i_p}_{j_1\cdots j_{x-1}j_{x+1}\cdots j_p} \tag{91}$$

$$\epsilon^{i_{p+1}\cdots i_M k_{M+1}\cdots k_N}_{i_{p+1}\cdots i_M j_{M+1}\cdots j_N} = \frac{M!}{p!}\epsilon^{k_{M+1}\cdots k_N}_{j_{M+1}\cdots j_N} \tag{92}$$

$$\epsilon^{k_{M+1}\cdots k_N}_{k'_{M+1}\cdots k'_N}\epsilon^{i_{p+1}\cdots i_M k'_{M+1}\cdots k'_N}_{j_{p+1}\cdots j_M l_{M+1}\cdots l_N} = (N-M)!\epsilon^{i_{p+1}\cdots i_M k_{M+1}\cdots k_N}_{j_{p+1}\cdots j_M l_{M+1}\cdots l_N} \tag{93}$$

A familiar special case of (91) is $\epsilon^{i_1 i_2}_{j_1 j_2} = \delta^{i_1}_{j_1}\delta^{i_2}_{j_2} - \delta^{i_1}_{j_2}\delta^{i_2}_{j_1}$. An example of the use of these identities that is relevant to the correlators computed in this paper is

$$\begin{aligned}\epsilon_{i_1\cdots i_N}\epsilon_{k_1\cdots k_N}\epsilon^{k_1\cdots k_p i_{p+1}\cdots i_N}\epsilon^{i_1\cdots i_p k_{p+1}\cdots k_N} &= \epsilon^{k_1\cdots k_p i_{p+1}\cdots i_N}_{i_1\cdots i_N}\epsilon^{i_1\cdots i_p k_{p+1}\cdots k_N}_{k_1\cdots k_N} \\ &= (N-p)!^2\epsilon^{k_1\cdots k_p}_{i_1\cdots i_p}\epsilon^{i_1\cdots i_p}_{k_1\cdots k_p}(N-p)!p!N!\end{aligned}$$

Another useful summation formula is ($M \le N$)

$$\sum_{p=0}^{M}\frac{(N-p)!}{(M-p)!} = \frac{(N+1)!}{(N-M+1)M!}\,. \tag{94}$$

In some computations we only need to keep terms to leading order in large N. Assuming M and N are of the same order (so that $M = \alpha N$ with $0 < \alpha < 1$) it can be shown that at leading order in N

$$\sum_{p=0}^{M}\frac{(N-p)!}{(M-p)!}p^k \sim \sum_{p=0}^{M}\frac{(N-p)!}{(M-p)!} = \frac{(N+1)!}{(N-M+1)M!} \sim \frac{N!}{M!} \tag{95}$$

This tells us the factor of p^k only contributes a coefficient of proportionality at the leading order in large N.

B Young operators for two column Young diagrams

In Sec. 5 we gave general expressions for the Young operators associated to a Young diagram. However, it can be difficult in general to construct a concrete closed form expression. In this appendix we explicitly derive the operators describing two branes with one string on them. The relevant Young diagrams appear in Fig. 7, and consist of two columns with N and M boxes ($M \le N$). Operators are constructed by filling one box with Y^J and all remaining boxes with Φ. As discussed in Sec. 5 and Sec. 6, there are two independent states of this form, which we construct below.

B.1 String attached to the smaller brane

First, we construct the operator corresponding to the first tableau (1) in Fig. 7, i.e., an open string attached to the smaller brane. Recall from Sec. 5 that must fill the boxes of the tableau and then symmetrize rows and antisymmetrize columns. It is easiest to start with the antisymmetrization. Taking the product of an antisymmetric combination of N Φs with an antisymmetric combination of $M-1$ Φs and one Y^J gives the operator

$$P_1 \equiv \epsilon^{i_1 i_2 \ldots i_N}_{j_1 j_2 \ldots j_N}\Phi^{j_1}_{i_1}\Phi^{j_2}_{i_2}\ldots\Phi^{j_N}_{i_N}\epsilon^{\tilde{i}_1\tilde{i}_2\ldots\tilde{i}_M\tilde{k}_1\ldots\tilde{k}_{N-M}}_{\tilde{j}_1\tilde{j}_2\ldots\tilde{j}_M\tilde{k}_1\ldots\tilde{k}_{N-M}}\Phi^{\tilde{j}_1}_{\tilde{i}_1}\Phi^{\tilde{j}_2}_{\tilde{i}_2}\ldots\Phi^{\tilde{j}_{M-1}}_{\tilde{i}_{M-1}}(Y^J)^{\tilde{j}_M}_{\tilde{i}_M} \tag{96}$$

It remains to act with the horizontal Young subgroup, i.e., to symmetrize the rows of the tableau.

To start, we reorganize the sum over $\widetilde{i}_1$ as

$$\begin{aligned} P_1 &= \sum_{\widetilde{i}_1=i_l,l=1}^{N} \epsilon^{i_1 i_2 \dots i_N}_{j_1 j_2 \dots j_N} \Phi^{j_1}_{i_1} \Phi^{j_2}_{i_2} \dots \Phi^{j_N}_{i_N} \epsilon^{i_l \widetilde{i}_2 \dots \widetilde{i}_M \widetilde{k}_1 \dots \widetilde{k}_{N-M}}_{\widetilde{j}_1 \widetilde{j}_2 \dots \widetilde{j}_M \widetilde{k}_1 \dots \widetilde{k}_{N-M}} \Phi^{\widetilde{j}_1}_{i_l} \Phi^{\widetilde{j}_2}_{\widetilde{i}_2} \dots \Phi^{\widetilde{j}_{M-1}}_{\widetilde{i}_{M-1}} (Y^J)^{\widetilde{j}_M}_{\widetilde{i}_M} \\ &= N \epsilon^{i_1 i_2 \dots i_N}_{j_1 j_2 \dots j_N} \Phi^{j_1}_{i_1} \Phi^{j_2}_{i_2} \dots \Phi^{j_N}_{i_N} \epsilon^{i_1 \widetilde{i}_2 \dots \widetilde{i}_M \widetilde{k}_1 \dots \widetilde{k}_{N-M}}_{\widetilde{j}_1 \widetilde{j}_2 \dots \widetilde{j}_M \widetilde{k}_1 \dots \widetilde{k}_{N-M}} \Phi^{\widetilde{j}_1}_{i_1} \Phi^{\widetilde{j}_2}_{\widetilde{i}_2} \dots \Phi^{\widetilde{j}_{M-1}}_{\widetilde{i}_{M-1}} (Y^J)^{\widetilde{j}_M}_{\widetilde{i}_M} \\ &\equiv N P_{1,1}\,. \end{aligned}$$

Continuing this way and summing up $\widetilde{i}_1, ..., \widetilde{i}_k$ gives

$$P_1 = N(N-1)...(N-k+1)P_{1,k} \tag{97}$$

$$P_{1,k} = \epsilon^{i_1 i_2 \dots i_N}_{j_1 j_2 \dots j_N} \Phi^{j_1}_{i_1} \Phi^{j_2}_{i_2} \dots \Phi^{j_N}_{i_N} \epsilon^{i_1 \dots i_k \widetilde{i}_{k+1} \dots \widetilde{i}_M \widetilde{k}_1 \dots \widetilde{k}_{N-M}}_{\widetilde{j}_1 \dots \widetilde{j}_k \widetilde{j}_{k+1} \dots \widetilde{j}_M \widetilde{k}_1 \dots \widetilde{k}_{N-M}} \Phi^{\widetilde{j}_1}_{i_1} \dots \Phi^{\widetilde{j}_k}_{i_k} \Phi^{\widetilde{j}_{k+1}}_{\widetilde{i}_{k+1}} \dots \Phi^{\widetilde{j}_{M-1}}_{\widetilde{i}_{M-1}} (Y^J)^{\widetilde{j}_M}_{\widetilde{i}_M} \tag{98}$$

Now consider symmetrizing by action of the horizontal group of the tableau. Because we have only two columns, all elements of the horizontal group are of the form $(i_{l_1}\widetilde{i}_{l_1})...(i_{l_k}\widetilde{i}_{l_k})$ where $(i_{l_1}\widetilde{i}_{l_1})$ exchanges i_{l_1} and $\widetilde{i}_{l_1}$. A single permutation by $(i_1\widetilde{i}_1)$, for example, gives

$$(i_1\widetilde{i}_1) \cdot P_1 = \epsilon^{i_1 i_2 \dots i_N}_{j_1 j_2 \dots j_N} \Phi^{j_1}_{\widetilde{i}_1} \Phi^{j_2}_{i_2} \dots \Phi^{j_N}_{i_N} \epsilon^{\widetilde{i}_1 \widetilde{i}_2 \dots \widetilde{i}_M \widetilde{k}_1 \dots \widetilde{k}_{N-M}}_{\widetilde{j}_1 \widetilde{j}_2 \dots \widetilde{j}_M \widetilde{k}_1 \dots \widetilde{k}_{N-M}} \Phi^{\widetilde{j}_1}_{i_1} \Phi^{\widetilde{j}_2}_{\widetilde{i}_2} \dots \Phi^{\widetilde{j}_{M-1}}_{\widetilde{i}_{M-1}} (Y^J)^{\widetilde{j}_M}_{\widetilde{i}_M}$$

It is important that we permute indices before summing over them. Upon summing over $\widetilde{i}_1$ on the right hand side, the expression vanishes unless $\widetilde{i}_1 = i_1$ because of antisymmetry under the j indices. Thus,

$$(i_1\widetilde{i}_1) \cdot P_1 = \epsilon^{i_1 i_2 \dots i_N}_{j_1 j_2 \dots j_N} \Phi^{j_1}_{i_1} \Phi^{j_2}_{i_2} \dots \Phi^{j_N}_{i_N} \epsilon^{i_1 \widetilde{i}_2 \dots \widetilde{i}_M \widetilde{k}_1 \dots \widetilde{k}_{N-M}}_{\widetilde{j}_1 \widetilde{j}_2 \dots \widetilde{j}_M \widetilde{k}_1 \dots \widetilde{k}_{N-M}} \Phi^{\widetilde{j}_1}_{i_1} \Phi^{\widetilde{j}_2}_{\widetilde{i}_2} \dots \Phi^{\widetilde{j}_{M-1}}_{\widetilde{i}_{M-1}} (Y^J)^{\widetilde{j}_M}_{\widetilde{i}_M} = P_{1,1} = \frac{1}{N} P_1$$

Iterating this process,

$$\prod_{l=1}^{k} (i_l\widetilde{i}_l) \cdot P_1 = k! P_{1,k} = k! \frac{(N-k)!}{N!} P_1 \equiv \frac{1}{C_N^k} P_1 \tag{99}$$

Now it is straight forward to find carry out the symmetrization. The horizontal group action is $G = \prod_{l=1}^{M}(I + (i_l\widetilde{i}_l))$. Because (99) shows that the action of any product of pair permutations on P_1 is proportional to P_1 with a coefficient that depends on the number of permutations, we can write $G \cdot P_1 = \left(\sum_{s=0}^{M} C_M^s P^s\right) \cdot P_1$, where P^s simply denotes the action of any s pair permutations and C_M^s is the number of ways of selecting these permutations from the M that appear in the product defining G.

Then, using (99),

$$
\begin{aligned}
\mathcal{O}_1 &= \prod_{l=1}^{M}(I+(i_l\widetilde{i}_l))\cdot P_1 = \left(\sum_{s=0}^{M} C_M^s P^s\right)\cdot P_1 \\
&= \sum_{s=0}^{M} C_M^s \frac{1}{C_N^s} P_1 = \frac{M!}{N!} P_1 \sum_{s=0}^{M} \frac{(N-s)!}{(M-s)!} \\
&= \frac{(N+1)}{(N-M+1)} P_1 \qquad (100)
\end{aligned}
$$

where we have used (94).

B.2 String attached to the larger brane

A string in the larger brane is created by inserting a Y^J is the first column (which has N boxes) of the two column tableau, i.e., this is the second tableau (2) in Fig. 7. As above, it is easiest to start with a product operator that has taken care of anti-symmetrization by the vertical Young subgroup:

$$
P_2 = \epsilon^{i_1 i_2 \ldots i_N}_{j_1 j_2 \ldots j_N} \Phi^{j_1}_{i_1} \Phi^{j_2}_{i_2} \ldots \Phi^{j_{N-1}}_{i_{N-1}} (Y^J)^{j_N}_{i_N} \epsilon^{\widetilde{i}_1 \widetilde{i}_2 \ldots \widetilde{i}_M \widetilde{k}_1 \ldots \widetilde{k}_{N-M}}_{\widetilde{j}_1 \widetilde{j}_2 \ldots \widetilde{j}_M \widetilde{k}_1 \ldots \widetilde{k}_{N-M}} \Phi^{\widetilde{j}_1}_{\widetilde{i}_1} \Phi^{\widetilde{j}_2}_{\widetilde{i}_2} \ldots \Phi^{\widetilde{j}_M}_{\widetilde{i}_M} \qquad (101)
$$

Following the strategy (97) to sum over $\widetilde{i}_1, \ldots, \widetilde{i}_k$ gives

$$
P_2 = \frac{(N-1)!}{(N-k-1)!} P_{2,k,a} + \frac{k(N-1)!}{(N-k)!} P_{2,k,b} \qquad (102)
$$

where we have defined

$$
\begin{aligned}
P_{2,k,a} &= \epsilon^{i_1 i_2 \ldots i_N}_{j_1 j_2 \ldots j_N} \Phi^{j_1}_{i_1} \Phi^{j_2}_{i_2} \ldots \Phi^{j_{N-1}}_{i_{N-1}} (Y^J)^{j_N}_{i_N} \epsilon^{i_1 \ldots i_k \widetilde{i}_{k+1} \ldots \widetilde{i}_M \widetilde{k}_1 \ldots \widetilde{k}_{N-M}}_{\widetilde{j}_1 \ldots \widetilde{j}_k \widetilde{j}_{k+1} \ldots \widetilde{j}_M \widetilde{k}_1 \ldots \widetilde{k}_{N-M}} \Phi^{\widetilde{j}_1}_{i_1} \ldots \Phi^{\widetilde{j}_k}_{i_k} \Phi^{\widetilde{j}_{k+1}}_{\widetilde{i}_{k+1}} \ldots \Phi^{\widetilde{j}_M}_{\widetilde{i}_M} \\
P_{2,k,b} &= \epsilon^{i_1 i_2 \ldots i_N}_{j_1 j_2 \ldots j_N} \Phi^{j_1}_{i_1} \Phi^{j_2}_{i_2} \ldots \Phi^{j_{N-1}}_{i_{N-1}} (Y^J)^{j_N}_{i_N} \epsilon^{i_1 \ldots i_{k-1} i_N \widetilde{i}_{k+1} \ldots \widetilde{i}_M \widetilde{k}_1 \ldots \widetilde{k}_{N-M}}_{\widetilde{j}_1 \ldots \widetilde{j}_{k-1} \cdot \widetilde{j}_k \widetilde{j}_{k+1} \ldots \widetilde{j}_M \widetilde{k}_1 \ldots \widetilde{k}_{N-M}} \Phi^{\widetilde{j}_1}_{i_1} \ldots \Phi^{\widetilde{j}_{k-1}}_{i_{k-1}} \Phi^{\widetilde{j}_k}_{i_N} \Phi^{\widetilde{j}_{k+1}}_{\widetilde{i}_{k+1}} \ldots \Phi^{\widetilde{j}_M}_{\widetilde{i}_M}
\end{aligned}
$$

The two index structures arise because in reorganizing the sums over $\widetilde{i}_m$ as sums over the i_l following (97), the index i_N is distinguished because it indexes Y^J. A useful identity that we can infer from the above is

$$
P_{2,1,b} = \frac{(N-1)!}{(N-k)!} P_{2,k,b}
$$

With these results in hand, we symmetrize by the horizontal subgroup. One permutation gives

$$
\begin{aligned}
(i_1\widetilde{i}_1)\cdot P_2 &= P_{2,1,a} + P_{2,1,c} \\
P_{2,1,c} &= \epsilon^{i_1 i_2 \ldots i_N}_{j_1 j_2 \ldots j_N} \Phi^{j_1}_{i_N} \Phi^{j_2}_{i_2} \ldots \Phi^{j_{N-1}}_{i_{N-1}} (Y^J)^{j_N}_{i_N} \epsilon^{i_N \widetilde{i}_2 \ldots \widetilde{i}_M \widetilde{k}_1 \ldots \widetilde{k}_{N-M}}_{\widetilde{j}_1 \widetilde{j}_2 \ldots \widetilde{j}_M \widetilde{k}_1 \ldots \widetilde{k}_{N-M}} \Phi^{\widetilde{j}_1}_{i_1} \Phi^{\widetilde{j}_2}_{\widetilde{i}_2} \ldots \Phi^{\widetilde{j}_M}_{\widetilde{i}_M}
\end{aligned}
$$

where we permuted i_i and $\widetilde{i}_1$ as in (99) and then observed that the sum over $\widetilde{i}_1$ will vanish unless $\widetilde{i}_1 = i_1$ or $\widetilde{i}_1 = i_N$. When applying further permutations to P_1 we will find the following definitions and identities useful:

$$\begin{aligned}
P_{2,k,c} &= \epsilon^{i_1 i_2 \ldots i_N}_{j_1 j_2 \ldots j_N} \Phi^{j_1}_{i_N} \Phi^{j_2}_{i_2} \ldots \Phi^{j_{N-1}}_{i_{N-1}} (Y^J)^{j_N}_{i_N} \epsilon^{i_N i_2 \ldots i_k \widetilde{i}_{k+1} \ldots \widetilde{i}_M \widetilde{k}_1 \ldots \widetilde{k}_{N-M}}_{\widetilde{j}_1 \widetilde{j}_2 \ldots \widetilde{j}_k \widetilde{j}_{k+1} \ldots \widetilde{j}_M \widetilde{k}_1 \ldots \widetilde{k}_{N-M}} \Phi^{\widetilde{j}_1}_{i_1} \Phi^{\widetilde{j}_2}_{i_2} \ldots \Phi^{\widetilde{j}_k}_{i_k} \Phi^{\widetilde{j}_{k+1}}_{\widetilde{i}_{k+1}} \ldots \Phi^{\widetilde{j}_M}_{\widetilde{i}_M} \\
P_{2,1,c} &= \frac{(N-2)!}{(N-k-1)!} P_{2,k,c} \qquad (103) \\
\frac{1}{N} P_1 &= P_{2,1,b} - (N-1) P_{2,1,c} \qquad (104)
\end{aligned}$$

Using these identities we find that

$$\begin{aligned}
\prod_{l=1}^{k} (i_l \widetilde{i}_l) \cdot P_2 = k! P_{2,k,a} + k k! P_{2,k,c} &= k! \frac{(N-k-1)!}{(N-1)!} \left[P_2 - k P_{2,1,b} \right] \\
&\quad + k k! \frac{(N-k-1)!}{(N-2)!} P_{2,1,c} \qquad (105)
\end{aligned}$$

Finally, we can calculate the Young operator, again using the fact that the action of s permutations on P_2 only depends on how many permutations are involved. Using P^k to denote the action of k permutations we find

$$\mathcal{O}_2 = \prod_{l=1}^{M} (I + (i_l \widetilde{i}_l)) \cdot P_2 = \left(\sum_{k=0}^{M} C^k_M P^k \right) \cdot P_2 \qquad (106)$$

Applying our accumulated results gives

$$\begin{aligned}
\mathcal{O}_2 &= \sum_{k=0}^{M} C^k_M \left[k! \frac{(N-k-1)!}{(N-1)!} \left[P_2 - k P_{2,1,b} \right] + k k! \frac{(N-k-1)!}{(N-2)!} P_{2,1,c} \right] \qquad (107) \\
&= \frac{N}{(N-M)} P_2 + \frac{MN(N-1)}{(N-M)(N-M+1)} P_{2,1,c} \\
&\quad - \frac{MN}{(N-M)(N-M+1)} P_{2,1,b} \qquad (108)
\end{aligned}$$

Finally using (104) we obtain

$$\mathcal{O}_2 = \frac{N}{(N-M)} P_2 - \frac{M}{(N-M)(N-M+1)} P_1 \qquad (109)$$

As we will show, this formula can also be derived by demanding orthogonality between the operators making strings on the big and small branes.

B.3 Orthogonality

Now we check the orthogonality of $\mathcal{O}_1$ and $\mathcal{O}_2$. Appendix C contains a general proof of orthogonality of operators creating single strings on an arbitrary system of D-branes.

After some tedious but straight forward calculations we find that in the planar limit of the free theory

$$\frac{\left\langle P_1 P_2^\dagger \right\rangle}{N^{J-1}} = \frac{N!^2 (N+1)!(N-1)!(N-M)!M!^2}{(N-M+1)(N-M+2)} \left[1 + \frac{(J-1)(N-M+1)}{NM}\right] \tag{110}$$

$$\frac{\left\langle P_2 P_2^\dagger \right\rangle}{N^{J-1}} = \frac{N!(N+1)!(N-1)!^2(N-M)!M!^2((N+1)(N-M)+N)}{(N-M+2)(N-M+1)} \left[1 + \frac{(J-1)(N+M)}{N(N+1)(N(N-M+2)-M)}\right] \tag{111}$$

$$\frac{\left\langle P_1 P_1^\dagger \right\rangle}{N^{J-1}} = \frac{N!^3 (N+1)!(N-M)!M!(M-1)!}{(N-M+2)} \left[1 + \frac{(J-1)(N-M+1)}{NM}\right] \tag{112}$$

In particular,[13]

$$\left\langle P_1 P_2^\dagger \right\rangle = \left\langle P_1 P_1^\dagger \right\rangle \frac{M}{N(N-M+1)} \tag{113}$$

so

$$\left\langle \mathcal{O}_1 \mathcal{O}_2^\dagger \right\rangle = 0$$

which is just what we expected. Although the explicit results presented above are for planar diagrams it is in fact easy to show that the orthogonality will hold at all orders in the $1/N$ exapansion of the free theory. The only thing that matters in the calculation is the contraction of the two different index structures of Y^J. A little thought shows that at each non-planar order, these contractions satisfy (113) and orthogonality of $O_{1,2}$ will follow.

C Orthogonality of one open string states

In this Appendix we demonstrate orthogonality of one open string states on arbitrary brane system, i.e, arbitrary Young diagram. Recall that the operator is given by

$$P_{R,p} = \sum_{s \in S_n} \sum_{i=1}^{d_p} D_R(s)_{ii} \cdot s \tag{114}$$

---

[13] It is worth nothing that when $M \to N$, $\left\langle P_1 P_1^\dagger \right\rangle$ does not approach $\left\langle P_2 P_2^\dagger \right\rangle$ exactly. Instead,

$$\frac{\left\langle P_1 P_1^\dagger \right\rangle - \left\langle P_2 P_2^\dagger \right\rangle}{\left\langle P_1 P_1^\dagger \right\rangle + \left\langle P_2 P_2^\dagger \right\rangle} = \frac{\frac{(J-1)}{N^2} - \frac{2(J-1)}{N(N+1)}}{2 + \frac{(J-1)}{N^2} + \frac{2(J-1)}{N(N+1)}}$$

which is zero in the large N limit. The slight discrepancy occurs because the contractions of ϵ tensors are slightly different when $M = N$ (since one of the columns of the Young diagram only has $N-1$ Φs). Thus the results above apply strictly to $M < N$.

where i is summing over the irreducible block p of S_{n-1} inside the representaton R of S_n. Also we have used the fact that there is unitary representation matrix with real number entries so $\overline{D}^R = D^R$. Acting with (114) on the fields we have the state

$$\begin{aligned} P_{R,p}(\Phi, Y^J) &= \sum_{s\in S_n}\sum_{i=1}^{d_p} D_R(s)_{ii} \sum_{I_i=1}^{N} \Phi^{I_1}_{I_{s(1)}} \Phi^{I_2}_{I_{s(2)}} ... \Phi^{I_{n-1}}_{I_{s(n-1)}} (Y^J)^{I_n}_{I_{s(n)}} && (115) \\ P^{\dagger}_{R,p}(\Phi, Y^J) &= \sum_{t\in S_n}\sum_{i=1}^{d_p} \overline{D}_R(s)_{ii} \sum_{J_i=1}^{N} (\Phi^{\dagger})^{J_{t(1)}}_{J_1} (\Phi^{\dagger})^{J_{t(2)}}_{J_2} ... (\Phi^{\dagger})^{J_{t(n-1)}}_{J_{n-1}} (Y^{J\dagger})^{J_{t(n)}}_{J_n} && (116) \end{aligned}$$

Note the exchange of up and down indices under the conjugation of (116).

C.1 The two point function for $J = 1$ case

Now we calculate the two point fuction as

$$\begin{aligned} I_2 &= \left\langle P_{R,p}(\Phi, Y) P^{\dagger}_{S,q}(\Phi, Y) \right\rangle \\ &= \sum_{I,J} \sum_{s,t\in S_n} \sum_{i,j} D_R(s)_{ii} \overline{D}_S(t)_{jj} \Phi^{I_1}_{I_{s(1)}} \Phi^{I_2}_{I_{s(2)}} ... \Phi^{I_{n-1}}_{I_{s(n-1)}} Y^{I_n}_{I_{s(n)}} (\Phi^{\dagger})^{J_{t(1)}}_{J_1} (\Phi^{\dagger})^{J_{t(2)}}_{J_2} ... (\Phi^{\dagger})^{J_{t(n-1)}}_{J_{n-1}} (Y^{\dagger})^{J_{t(n)}}_{J_n} \\ &= \sum_{I,J} \sum_{s,t\in S_n} \sum_{i,j} D_R(s)_{ii} \overline{D}_S(t)_{jj} \sum_{\alpha\in S_{n-1}} \left\langle \Phi^{I_1}_{I_{s(1)}} (\Phi^{\dagger})^{J_{t(\alpha(1))}}_{J_{\alpha(1)}} \right\rangle \left\langle \Phi^{I_{n-1}}_{I_{s(n-1)}} (\Phi^{\dagger})^{J_{t(\alpha(n-1))}}_{J_{\alpha(n-1)}} \right\rangle \left\langle Y^{I_n}_{I_{s(n)}} (Y^{\dagger})^{J_{t(n)}}_{J_n} \right\rangle \end{aligned}$$

where $\sum_{\alpha\in S_{n-1}}$ gives all possible contractions. Now using

$$\left\langle \Phi^i_j (\Phi^{\dagger})^k_l \right\rangle = \delta^i_l \delta^k_j \frac{2\pi g_s}{4\pi^2} \frac{1}{|x-y|^2}$$

we get (we have neglected the factor $\frac{2\pi g_s}{4\pi^2}\frac{1}{|x-y|^2}$)

$$\begin{aligned} I_2 &= \sum_{I,J} \sum_{s,t\in S_n} \sum_{i,j} D_R(s)_{ii} \overline{D}_S(t)_{jj} \sum_{\alpha\in S_{n-1}} \delta^{I_l}_{J_{\alpha(l)}} \delta^{J_{t(\alpha(l))}}_{I_{s(l)}} \delta^{I_n}_{J_n} \delta^{J_{t(n)}}_{I_{s(n)}} \\ &= \sum_{I,J} \sum_{s,t\in S_n} \sum_{i,j} D_R(s)_{ii} \overline{D}_S(t)_{jj} \sum_{\alpha\in S_n|_{\alpha(n)=n}} \delta^{I_l}_{J_{\alpha(l)}} \delta^{J_{t(\alpha(l))}}_{I_{s(l)}} \\ &= \sum_{I,J} \sum_{s,t\in S_n} \sum_{i,j} D_R(s)_{ii} \overline{D}_S(t)_{jj} \sum_{\alpha\in S_n|_{\alpha(n)=n}} \delta^{I_{s(l)}}_{J_{\alpha(s(l))}} \delta^{J_{t(\alpha(l))}}_{I_{s(l)}} \\ &= \sum_{J} \sum_{s,t\in S_n} \sum_{i,j} D_R(s)_{ii} \overline{D}_S(t)_{jj} \sum_{\alpha\in S_n|_{\alpha(n)=n}} \delta^{J_{t(\alpha(l))}}_{J_{\alpha(s(l))}} \\ &= \sum_{s,t\in S_n} \sum_{i,j} D_R(s)_{ii} \overline{D}_S(t)_{jj} \sum_{\alpha\in S_n|_{\alpha(n)=n}} N^{C(\alpha^{-1}\cdot t^{-1}\cdot\alpha\cdot s)} \end{aligned}$$

where we have used some results from [7]. Inserting the delta-function

$$\begin{aligned}
I_2 &= \sum_{s,t\in S_n}\sum_{i,j} D_R(s)_{ii}\overline{D}_S(t)_{jj} \sum_{\alpha\in S_n|_{\alpha(n)=n}} \sum_{\beta\in S_n} N^{C(\beta)}\delta(\beta^{-1}\cdot\alpha^{-1}\cdot t^{-1}\cdot\alpha\cdot s) \\
&= \sum_{t\in S_n}\sum_{i,j} \sum_{\alpha\in S_n|_{\alpha(n)=n}} \sum_{\beta\in S_n} D_R(\alpha^{-1}t\alpha\beta)_{ii}\overline{D}_S(t)_{jj}N^{C(\beta)} \\
&= \sum_{\alpha\in S_n|_{\alpha(n)=n}} \sum_{\beta\in S_n}\sum_{i,j} N^{C(\beta)} \sum_{k,l=1}^{d_R}\sum_{t\in S_n} D_R(\alpha^{-1})_{ik}D_R(t)_{kl}D_R(\alpha\beta)_{li}\overline{D}_S(t)_{jj}
\end{aligned}$$

Finally we use the orthogonality relation

$$\sum_{g\in G} T^{\mu}_{il}(g)\overline{T^{\nu}_{sm}}(g) = \frac{d_G}{d_\mu}\delta_{is}\delta_{lm}\delta_{\mu\nu}$$

to get

$$\begin{aligned}
I_2 &= \sum_{\alpha\in S_n|_{\alpha(n)=n}} \sum_{\beta\in S_n}\sum_{i,j} N^{C(\beta)} \sum_{k,l} D_R(\alpha^{-1})_{ik}D_R(\alpha\beta)_{li}\frac{n!}{d_R}\delta_{RS}\delta_{kj}\delta_{lj} \\
&= \sum_{\alpha\in S_n|_{\alpha(n)=n}} \sum_{\beta\in S_n}\sum_{i=1}^{d_p}\sum_{j=1}^{d_q} N^{C(\beta)} D_R(\alpha^{-1})_{ij}D_R(\alpha\beta)_{ji}\frac{n!}{d_R}\delta_{RS} \qquad (117)
\end{aligned}$$

From the result (117) we can already read out some orthogonality relationships:

- (1) If $R \neq S$, I_2 is zero. In another words, open string states are orthogonal if they attach to different brane systems R and S.

- (2) If $R = S$, but $p \neq q$, I_2 is zero. This can be read out from $D_R(\alpha^{-1})_{ij}$. Since $\alpha^{-1}(n) = n$, we have $\alpha^{-1} \in S_{n-1} \subset S_n$. In the basis we have chosen, the matrix form is block diagonal so that $D_R(\alpha^{-1})_{ij} = 0$ if $p \neq q$. This proves the orthogonality of different open string states attaching to same giant system at tree level.

- (3) If $R = S$ and $p = q$ we can contiue the calculation as follows

$$\begin{aligned}
I_2 &= \sum_{\alpha\in S_n|_{\alpha(n)=n}} \sum_{\beta\in S_n}\sum_{i,j} N^{C(\beta)} D_R(\alpha^{-1})_{ij}D_R(\alpha\beta)_{ji}\frac{n!}{d_R}\delta_{RS} \\
&= \sum_{\alpha\in S_n|_{\alpha(n)=n}} \sum_{\beta\in S_n}\sum_{i} N^{C(\beta)} D_R(\beta)_{ii}\frac{n!}{d_R}\delta_{RS} \\
&= \frac{n!(n-1)!}{d_R}\delta_{RS}\sum_{\beta\in S_n} N^{C(\beta)}\sum_{i=1}^{d_p} D_R(\beta)_{ii}
\end{aligned}$$

C.2 The two point function with $J > 1$

For $J > 1$ a new term shows up in contractions of Y as

$$\left\langle (Y^m)^{I_n}_{I_{s(n)}} (Y^{m\dagger})^{J_{t(n)}}_{J_n} \right\rangle \sim N^{m-1} \delta^{I_n}_{J_n} \delta^{J_{t(n)}}_{I_{s(n)}} + (m-1) N^{m-2} \delta^{I_n}_{I_{s(n)}} \delta^{J_{t(n)}}_{J_n}$$

Thus we have

$$\begin{aligned} I_2 &= I_{2,a} + I_{2,b} \\ I_{2,a} &= N^{m-1} \sum_{I,J} \sum_{s,t\in S_n} \sum_{i,j} D_R(s)_{ii} \overline{D}_S(t)_{jj} \sum_{\alpha\in S_{n-1}} \delta^{I_l}_{J_{\alpha(l)}} \delta^{J_{t(\alpha(l))}}_{I_{s(l)}} \delta^{I_n}_{J_n} \delta^{J_{t(n)}}_{I_{s(n)}} \\ I_{2,b} &= (m-1) N^{m-2} \sum_{I,J} \sum_{s,t\in S_n} \sum_{i,j} D_R(s)_{ii} \overline{D}_S(t)_{jj} \sum_{\alpha\in S_{n-1}} \delta^{I_l}_{J_{\alpha(l)}} \delta^{J_{t(\alpha(l))}}_{I_{s(l)}} \delta^{I_n}_{I_{s(n)}} \delta^{J_{t(n)}}_{J_n} \end{aligned}$$

It is easy to see that $I_{2,a}$ is identical to previous calculations and we get

$$I_{2,a} = N^{m-1} \frac{n!(n-1)!}{d_R} \delta_{RS} \delta_{pq} \sum_{\beta\in S_n} N^{C(\beta)} \sum_{i}^{d_p} D_R(\beta)_{ii}$$

The remaining hard part is to calculate $I_{2,b}$. To do this we need to sum up

$$A_2 = \sum_{I,J} \delta^{I_1}_{J_{\alpha(1)}} \delta^{I_2}_{J_{\alpha(2)}} \ldots \delta^{I_{n-1}}_{J_{\alpha(n-1)}} \delta^{J_{t(\alpha(1))}}_{I_{s(1)}} \delta^{J_{t(\alpha(2))}}_{I_{s(2)}} \ldots \delta^{J_{t(\alpha(n-1))}}_{I_{s(n-1)}} \delta^{I_n}_{I_{s(n)}} \delta^{J_{t(n)}}_{J_n}$$

If we combine all indices together and treat group elements as permutation of S_{2n}, we can write A_2 as $(I_{s(n)} J_n) \cdot A_1$ where the permutation A_1 is given as

$$A_1 = \sum_{I,J} \delta^{I_1}_{J_{\alpha(1)}} \delta^{I_2}_{J_{\alpha(2)}} \ldots \delta^{I_{n-1}}_{J_{\alpha(n-1)}} \delta^{I_n}_{J_n} \delta^{J_{t(\alpha(1))}}_{I_{s(1)}} \delta^{J_{t(\alpha(2))}}_{I_{s(2)}} \ldots \delta^{J_{t(\alpha(n-1))}}_{I_{s(n-1)}} \delta^{J_{t(n)}}_{I_{s(n)}}$$

Now we can see how the cycle structure changes from A_1 to A_2 under the permutation $(I_{s(n)} J_n)$:

- (1) If cycles of A_1 do not contain $I_{s(n)}$ and J_n, they are invariant under the permutation $(I_{s(n)} J_n)$. Because I_n and J_n are always in the same cycle of S_{2n}, when we reduce to the cycle structure of S_n, the cycles of $s\alpha^{-1}t^{-1}\alpha$ do not have elements (n) and $s(n)$.
- (2) If $I_{s(n)}$ and J_n belong to two different cycles of A_1, after the permutation $(I_{s(n)} J_n)$, these two cycles will combine to one cycle. From the point of view of S_n, it means that one cycle of $s\alpha^{-1}t^{-1}\alpha$ has element (n) and another cycle, $s(n)$. These two cycles will merge by permutation $(ns(n))$ of S_n.

- (3) If $I_{s(n)}$ and J_n belong to same cycles of A_1, after the permutation $(I_{s(n)}J_n)$, this cycle will break to two cylces. From the point of view of S_n, it means that this cycle of $s\alpha^{-1}t^{-1}\alpha$ has both elements (n) and $s(n)$ and it will be broken to two cycle by permutation $(ns(n))$ of S_n.

All above analyses can be summarized as

$$A_2 \quad = \quad N^{C(P_s s\alpha^{-1}t^{-1}\alpha)}$$

where $P_s = (n, s(n))$ is the permutation determined by s. It is worth to notice that $P_s(s(n)) = n$ or $P_s s \in S_{n-1}$. Using this we can write $\sum_{s\in S_n} s \sum_{i=1}^{n} \sum_{\widetilde{s}\in S_{n-1}} P_i\widetilde{s}$ with $P_i = (i, n)$.

Now we can calculate

$$\begin{aligned}
I_{2,b} &= (m-1)N^{m-2} \sum_{\alpha\in S_{n-1}} \sum_{s,t\in S_n} \sum_{i,j} D_R(s)_{ii}\overline{D}_S(t)_{jj} N^{C(P_s s\alpha^{-1}t^{-1}\alpha)} \\
&= (m-1)N^{m-2} \sum_{\alpha\in S_{n-1}} \sum_{i=1}^{n} \sum_{\widetilde{s}\in S_{n-1}} \sum_{t\in S_n} \sum_{i,j} D_R(P_i\widetilde{s})_{ii}\overline{D}_S(t)_{jj} N^{C(\widetilde{s}\alpha^{-1}t^{-1}\alpha)} \\
&= (m-1)N^{m-2} \sum_{\alpha\in S_{n-1}} \sum_{k=1}^{n} \sum_{\widetilde{s}\in S_{n-1}} \sum_{t\in S_n} \sum_{i,j} D_R(P_k\widetilde{s})_{ii}\overline{D}_S(t)_{jj} \sum_{\beta\in S_n} N^{C(\beta)}\delta(\beta^{-1}\widetilde{s}\alpha^{-1}t^{-1}\alpha) \\
&= (m-1)N^{m-2} \sum_{\alpha\in S_{n-1}} \sum_{\beta\in S_n} N^{C(\beta)} \sum_{k=1}^{n} \sum_{\widetilde{s}\in S_{n-1}} \sum_{i,j} D_R(P_k\widetilde{s})_{ii}\overline{D}_S(\alpha\beta^{-1}\widetilde{s}\alpha^{-1})_{jj} \\
&= (m-1)N^{m-2} \sum_{\alpha\in S_{n-1}} \sum_{\beta\in S_n} N^{C(\beta)} \sum_{k=1}^{n} \sum_{\widetilde{s}\in S_{n-1}} \sum_{i,j} \\
&\quad \sum_{l,m}^{d_S} \sum_{r}^{d_R} D_R(P_k)_{ir} D_R(\widetilde{s})_{ri} \overline{D}_S(\alpha\beta^{-1})_{jl} \overline{D}_S(\widetilde{s})_{lm} \overline{D}_S(\alpha^{-1})_{mj}
\end{aligned}$$

Note that from the third equation to the fourth equation we sum $t \in S_n$ instead of $\widetilde{s} \in S_{n-1}$ because the equation $\beta^{-1}\widetilde{s}\alpha^{-1}t^{-1}\alpha = I$ may not have a solution for all $\widetilde{s} \in S_{n-1}$. Now we can use the orthogonality relationship for $\widetilde{s} \in S_{n-1}$. However, the situation is a little complex because the representations R, S are irreducible to S_n, but reducible (most time) to S_{n-1}. In our choice of bases, the matrix is block diagonazed for $\widetilde{s} \in S_{n-1}$, thus we have $\sum_{r}^{d_R} D_R(\widetilde{s})_{ri} = \sum_{r}^{d_p} D_R(\widetilde{s})_{ri}$ where p is the irreducible representation of S_{n-1} inside R. Similarly $\sum_{l,m}^{d_S} \overline{D}_S(\widetilde{s})_{lm} = \sum_{q_\gamma} \sum_{l_\gamma,m_\gamma}^{d_\gamma} \overline{D}_S(\widetilde{s})_{l_\gamma m_\gamma}$ where q_γ are these irreducible representations of S_{n-1} inside representation S. Now using

$$\sum_{\widetilde{s}\in S_{n-1}} D_R(\widetilde{s})_{ri}\overline{D}_S(\widetilde{s})_{l_\gamma m_\gamma} \quad = \quad \frac{(n-1)!}{d_p}\delta_{pq_\gamma}\delta_{rl_\gamma}\delta_{im_\gamma}$$

we have

$$\begin{aligned} I_{2,b} &= \frac{(n-1)!(m-1)N^{m-2}}{d_p} \sum_{\alpha \in S_{n-1}} \sum_{\beta \in S_n} N^{C(\beta)} \sum_{k=1}^{n} \sum_{i,j} \\ &\sum_{r}^{d_p} \sum_{q_\gamma} \sum_{l_\gamma, m_\gamma}^{d_\gamma} D_R(P_k)_{ir} \overline{D}_S(\alpha\beta^{-1})_{jl_\gamma} \overline{D}_S(\alpha^{-1})_{m_\gamma j} \delta_{pq_\gamma} \delta_{rl_\gamma} \delta_{im_\gamma} \end{aligned}$$

Notice that $\alpha^{-1} \in S_{n-1}$, $\overline{D}_S(\alpha^{-1})_{m_\gamma j}$ is not zero when and only when q_γ is the same irreducible representation q chosen by index j (our starting point). Thus we have

$$\begin{aligned} I_{2,b} &= \frac{(n-1)!(m-1)N^{m-2}}{d_p} \sum_{\alpha \in S_{n-1}} \sum_{\beta \in S_n} N^{C(\beta)} \sum_{k=1}^{n} \sum_{i,j} \\ &\sum_{r}^{d_p} \sum_{l,m}^{d_q} D_R(P_k)_{ir} \overline{D}_S(\alpha\beta^{-1})_{jl} \overline{D}_S(\alpha^{-1})_{mj} \delta_{pq} \delta_{rl} \delta_{im} \\ &= \frac{(n-1)!(m-1)N^{m-2}}{d_p} \sum_{\alpha \in S_{n-1}} \sum_{\beta \in S_n} N^{C(\beta)} \sum_{k=1}^{n} \sum_{i} \\ &\sum_{r}^{d_p} \sum_{l,m}^{d_q} D_R(P_k)_{ir} \overline{D}_S(\alpha^{-1}\alpha\beta^{-1})_{ml} \delta_{pq} \delta_{rl} \delta_{im} \\ &= \frac{(n-1)!(n-1)!(m-1)N^{m-2}}{d_p} \delta_{pq} \sum_{\beta \in S_n} N^{C(\beta)} \sum_{k=1}^{n} \sum_{i}^{d_p} \sum_{l}^{d_q} D_{R,p}(P_k\beta)_{ii} \end{aligned}$$

Result $I_{2,b}$ tell us that the orthogonal relationship is not that perfect because even $R \neq S$, as long as $p \in R$, $q \in S$ and $p = q$ for S_{n-1} $I_{2,b}$ is still nozero.

Now the large N limit comes to be our rescue. Let us consider the ratio of $\frac{I_{2,b}}{I_{2,a}}$

$$\frac{I_{2,b}}{I_{2,a}} = \frac{d_R}{d_p} \frac{(m-1)}{Nn} \frac{\sum_{\beta \in S_n} N^{C(\beta)} \sum_{k=1}^{n} \sum_{i}^{d_p} \sum_{l}^{d_g} D_{R,p}(P_k)_{il} D_{S,q}(\beta)_{li}}{\sum_{\beta \in S_n} N^{C(\beta)} \sum_{i}^{d_p} D_R(\beta)_{ii}}$$

where $\frac{d_R}{d_p} \sim \mathcal{O}(1)$. The difficult part is to estimate the last ratio. Notice if $R = S$ we have $\sum_{i}^{d_p} \sum_{l}^{d_g} D_{R,p}(P_k)_{il} D_{S,q}(\beta)_{li} = \sum_{i}^{d_p} D_{R,p}(P_k\beta)_{ii}$, so it is not unreasonable to guess naively that $\sum_{k=1}^{n}$ will contribute an order n. If this assumption is right (which we do not know how to prove it), we have

$$\frac{I_{2,b}}{I_{2,a}} \sim \frac{(m-1)}{N}$$

Thus as long as the angular momentum m is not large enough, under proper normalization using $I_{2,a}$ we can neglect the contribution of $I_{2,b}$ and get the perfect orthogonal relationship, i.e, *if $R \neq S$ or $p \neq q$, two open string states are orthogonal.*

In principal, we can use similar method to prove the orthogonality for two open string states or more open string states. However, as the calculation becomes tedious very quickly, it is better to look for simpler method.

D An example

In this appendix we will give a detailed example of the correlation function computations in this paper. Other calculations are carried out similarly, but we omit the details here because of their length. As our example we will describe how to calculate the two-point functions of the operator P_1 (56) which describes two D-branes with a string on the smaller one. In the free theory the contractions of the fields in (56) give

$$\begin{aligned}\left\langle P_1 P_1^\dagger \right\rangle &= (N-M)!^2 \sum_{p=0}^{M-1} C_N^p C_N^p C_{M-1}^p C_{M-1}^p p!p!(N-p)!(M-1-p)! \\ &\times\ \epsilon^{i_1\ldots i_p i_{p+1}\ldots i_N}_{j_1\ldots j_p j_{p+1}\ldots. j_N} \epsilon^{\widetilde{i}_1\ldots \widetilde{i}_p \widetilde{i}_{p+1}\ldots \widetilde{i}_{M-1}\widetilde{i}_M}_{\widetilde{j}_1\ldots \widetilde{j}_p \widetilde{j}_{p+1}\ldots \widetilde{j}_{M-1}\widetilde{j}_M} \epsilon^{\widetilde{j}_1\ldots \widetilde{j}_p j_{p+1}\ldots j_N}_{\widetilde{i}_1\ldots \widetilde{i}_p i_{p+1}\ldots i_N} \epsilon^{j_1\ldots j_p \widetilde{j}_{p+1}\ldots \widetilde{j}_{M-1}\widetilde{k}_M}_{i_1\ldots i_p \widetilde{i}_{p+1}\ldots \widetilde{i}_{M-1}\widetilde{l}_M} \\ &\times\ \left[N^{J-1} \delta^{\widetilde{j}_M}_{\widetilde{k}_M} \delta^{\widetilde{l}_M}_{\widetilde{i}_M} + (J-1) N^{J-2} \delta^{\widetilde{j}_M}_{\widetilde{i}_M} \delta^{\widetilde{l}_M}_{\widetilde{k}_M} \right] \end{aligned} \tag{118}$$

Here p counts the number of Φ fields in the big brane of P_1 that are contracted with $\bar{\Phi}$ fields in the small brane of $P_1^\dagger$. The combinatorial factor $C_N^p C_N^p C_{M-1}^p C_{M-1}^p p!p!(N-p)!(M-1-p)!$ arises from the number of ways in which these contractions can be done. For example, choosing p Φ from the large brane in P_1 and p $\overline{\Phi}$ from small brane of $\overline{P}_1$ gives factor $C_N^p C_{M-1}^p$ while different orders of contractions among these two groups of Φ gives the factor $p!$. The contractions between Ys give two different index structures. While the contraction between the Φs are carried out exactly, those between the Ys are done at the planar level. In this sense our computations are at the leading order in large N. One loop corrections from interactions are also evaluated in the planar limit for contractions between Ys.

For the first index structure we have

$$\begin{aligned}\left\langle P_1 P_1^\dagger \right\rangle_a &= (N-M)!^2 N^{J-1} \sum_{p=0}^{M-1} C_N^p C_N^p C_{M-1}^p C_{M-1}^p p!p!(N-p)!(M-1-p)! \\ &\times\ \epsilon^{i_1\ldots i_p i_{p+1}\ldots i_N}_{j_1\ldots j_p j_{p+1}\ldots. j_N} \epsilon^{\widetilde{i}_1\ldots \widetilde{i}_p \widetilde{i}_{p+1}\ldots \widetilde{i}_{M-1}\widetilde{i}_M}_{\widetilde{j}_1\ldots \widetilde{j}_p \widetilde{j}_{p+1}\ldots \widetilde{j}_{M-1}\widetilde{j}_M} \epsilon^{\widetilde{j}_1\ldots \widetilde{j}_p j_{p+1}\ldots j_N}_{\widetilde{i}_1\ldots \widetilde{i}_p i_{p+1}\ldots i_N} \epsilon^{j_1\ldots j_p \widetilde{j}_{p+1}\ldots \widetilde{j}_{M-1}\widetilde{j}_M}_{i_1\ldots i_p \widetilde{i}_{p+1}\ldots \widetilde{i}_{M-1}\widetilde{i}_M} \end{aligned} \tag{119}$$

We can interchange the lower indices of first and third ϵ tensors, because both of them are maximal to get

$$\begin{aligned}\left\langle P_1 P_1^\dagger \right\rangle_a &= (N-M)!^2 N^{J-1} \sum_{p=0}^{M-1} C_N^p C_N^p C_{M-1}^p C_{M-1}^p p!p!(N-p)!(M-1-p)! \\ &\times\ \epsilon^{i_1\ldots i_p i_{p+1}\ldots i_N}_{\widetilde{i}_1\ldots \widetilde{i}_p i_{p+1}\ldots i_N} \epsilon^{\widetilde{i}_1\ldots \widetilde{i}_p \widetilde{i}_{p+1}\ldots \widetilde{i}_{M-1}\widetilde{i}_M}_{\widetilde{j}_1\ldots \widetilde{j}_p \widetilde{j}_{p+1}\ldots \widetilde{j}_{M-1}\widetilde{j}_M} \epsilon^{\widetilde{j}_1\ldots \widetilde{j}_p j_{p+1}\ldots j_N}_{j_1\ldots j_p j_{p+1}\ldots. j_N} \epsilon^{j_1\ldots j_p \widetilde{j}_{p+1}\ldots \widetilde{j}_{M-1}\widetilde{j}_M}_{i_1\ldots i_p \widetilde{i}_{p+1}\ldots \widetilde{i}_{M-1}\widetilde{i}_M} \end{aligned} \tag{120}$$

Carrying out various index contractions using the identities in Appendix A gives

$$\begin{aligned}\left\langle P_1 P_1^\dagger \right\rangle_a &= N-M)!^2 N^{J-1} \sum_{p=0}^{M-1} C_N^p C_N^p C_{M-1}^p C_{M-1}^p p!p!(N-p)!(M-1-p)! \\ &\quad \times (N-p)!^2 \epsilon^{i_1\ldots i_p}_{\tilde{i}_1\ldots\tilde{i}_p} \epsilon^{\tilde{i}_1\ldots\tilde{i}_p\tilde{i}_{p+1}\ldots\tilde{i}_{M-1}\tilde{i}_M}_{\tilde{j}_1\ldots\tilde{j}_p\tilde{j}_{p+1}\ldots\tilde{j}_{M-1}\tilde{j}_M} \epsilon^{\tilde{j}_1\ldots\tilde{j}_p}_{j_1\ldots j_p} \epsilon^{j_1\ldots j_p\tilde{j}_{p+1}\ldots\tilde{j}_{M-1}\tilde{j}_M}_{i_1\ldots i_p\tilde{i}_{p+1}\ldots\tilde{i}_{M-1}\tilde{i}_M} \qquad (121) \\ &= (N-M)!^2 N^{J-1} \sum_{p=0}^{M-1} C_N^p C_N^p C_{M-1}^p C_{M-1}^p p!p!(N-p)!(M-1-p)! \\ &\quad \times (N-p)!^2 p!^2 \epsilon^{i_1\ldots i_p\tilde{i}_{p+1}\ldots\tilde{i}_{M-1}\tilde{i}_M}_{\tilde{j}_1\ldots\tilde{j}_p\tilde{j}_{p+1}\ldots\tilde{j}_{M-1}\tilde{j}_M} \epsilon^{\tilde{j}_1\ldots\tilde{j}_p\tilde{j}_{p+1}\ldots\tilde{j}_{M-1}\tilde{j}_M}_{i_1\ldots i_p\tilde{i}_{p+1}\ldots\tilde{i}_{M-1}\tilde{i}_M} \qquad (122)\end{aligned}$$

Further simplification leads to

$$\begin{aligned}\left\langle P_1 P_1^\dagger \right\rangle_a &= (N-M)!^2 N^{J-1} \sum_{p=0}^{M-1} C_N^p C_N^p C_{M-1}^p C_{M-1}^p p!p!(N-p)!(M-1-p)! \\ &\quad \times (N-p)!^2 p!^2 M! \frac{N!}{(N-M)!} \qquad (123) \\ &= N^{J-1} N!^3 (N-M)! M! (M-1)!^2 \sum_{p=0}^{M-1} \frac{(N-p)!}{(M-1-p)!} \qquad (124) \\ &= N^{J-1} N!^3 (N-M)! M! (M-1)!^2 \frac{(N+1)!}{(N-M+2)(M-1)!} \qquad (125)\end{aligned}$$

In this particular case the final index contractions in (122) were simple. However, the $\left\langle P_1 P_1^\dagger \right\rangle$ has two index structures. If we evaluate the second index structure $(J-1)N^{J-2}\delta^{\tilde{j}_M}_{\tilde{i}_M}\delta^{\tilde{l}_M}_{\tilde{k}_M}$ we will meet following index contractions

$$\begin{aligned}\mathcal{E}_{II} &\equiv \epsilon^{j_p j_{N-p-1} j}_{i_p i_{N-p-1} j} \overline{\epsilon}^{k_p i_{N-p-1} i}_{l_p j_{N-p-1} i} \epsilon^{l_p l_{M-p}}_{k_p k_{M-p}} \overline{\epsilon}^{i_p k_{M-p}}_{j_p l_{M-p}} = \epsilon^{j_p j_{N-p-1} j}_{l_p j_{N-p-1} i} \overline{\epsilon}^{k_p i_{N-p-1} i}_{i_p i_{N-p-1} j} \epsilon^{l_p l_{M-p}}_{k_p k_{M-p}} \overline{\epsilon}^{i_p k_{M-p}}_{j_p l_{M-p}} \\ &= (N-p-1)!^2 \epsilon^{j_p j}_{l_p i} \overline{\epsilon}^{k_p i}_{i_p j} \epsilon^{l_p l_{M-p}}_{k_p k_{M-p}} \overline{\epsilon}^{i_p k_{M-p}}_{j_p l_{M-p}}\end{aligned}$$

where we have used j_p to represent $j_1 \ldots j_p$ and k_{M-p} to represent $k_1 \ldots k_{M-p}$ to make notation simpler. The factor $\epsilon^{j_p j}_{l_p i} \overline{\epsilon}^{k_p i}_{i_p j} \epsilon^{l_p l_{M-p}}_{k_p k_{M-p}} \overline{\epsilon}^{i_p k_{M-p}}_{j_p l_{M-p}}$ can be computed step by step:

- (1) Fixing i we have N choices.
- (2) If $j = i$, then i_p, j_p, k_p, l_p can only choose from remaining $(N-1)$ values and we denote as $i_p, j_p, k_p, l_p \in U(N-1)$. Now l_{M-p}, k_{M-p} can have two realization. The first is that one index in the set l_{M-p}, k_{M-p} (recalling that these two sets have $(M-p)$ indices) take the value i. The second is that no index in the set l_{M-p}, k_{M-p} take the value i. For the first case we can write $l_{M-p} = i l_{M-p-1}$ and

$k_{M-p} = ik_{M-p-1}$ after some permutations. Thus we have

$$\begin{aligned}
& N(M-p)^2 \epsilon^{j_p}_{l_p} \bar{\epsilon}^{k_p}_{i_p} \epsilon^{l_p l_{M-p-1}}_{k_p k_{M-p-1}} \bar{\epsilon}^{i_p k_{M-p-1}}_{j_p l_{M-p-1}} \\
= \;& N(M-p)^2 p!^2 \epsilon^{j_p l_{M-p-1}}_{k_p k_{M-p-1}} \bar{\epsilon}^{k_p k_{M-p-1}}_{j_p l_{M-p-1}} \\
= \;& N(M-p)^2 p!^2 (M-1)! \frac{(N-1)!}{(N-1-(M-1))!} \\
= \;& \frac{N!(M-1)!p!^2(M-p)^2}{(N-M)!}
\end{aligned}$$

The factor N comes from summing i. The factor $(M-p)^2$ comes from the choice of one index from two sets l_{M-p}, k_{M-p}. Furthermore, when writting in above form we have neglected the index i. The purpose of doing so is because now every index can only take values from remaining $(N-1)$ values. In another word, we can treat above expression as the index contraction for $U(N-1)$ gauge group (recalling results in the Appendix A).

For the second case we have

$$\begin{aligned}
& N \epsilon^{j_p}_{l_p} \bar{\epsilon}^{k_p}_{i_p} \epsilon^{l_p l_{M-p}}_{k_p k_{M-p}} \bar{\epsilon}^{i_p k_{M-p-1}}_{j_p l_{M-p}} \\
= \;& N p!^2 \epsilon^{j_p l_{M-p}}_{k_p k_{M-p}} \bar{\epsilon}^{k_p k_{M-p}}_{j_p l_{M-p}} \\
= \;& N p!^2 M! \frac{(N-1)!}{(N-1-M)!} \\
= \;& \frac{N!(M-1)!p!^2 M(N-M)}{(N-M)!}
\end{aligned}$$

Adding these two cases together we have

$$\frac{N!(M-1)!p!^2}{(N-M)!}[(M-p)^2 + M(N-M)]$$

- (3). Now we discuss the case that $i \neq j$. It is obvious that we will have factor $N(N-1)$ from summing i, j. Since $\epsilon^{j_p j}_{l_p i}$ is zero unless $(l_p i)$ is a permutation of $(j_p j)$, this means that index j must show up in set l_p. Similarly i must show up in set j_p. After all we have $i \in j_p, i_p$, $j \in l_p, k_p$ with combinatorical factor p^4. Notice that $l_{M-p}, k_{M-p} \in U(N-2)$ so we reduced index contraction to

$$\begin{aligned}
& N(N-1)p^4 \epsilon^{j_{p-1}}_{l_{p-1}} \bar{\epsilon}^{k_{p-1}}_{i_{p-1}} \epsilon^{l_{p-1} l_{M-p}}_{k_{p-1} k_{M-p}} \bar{\epsilon}^{i_{p-1} k_{M-p-1}}_{j_{p-1} l_{M-p}} \\
= \;& N(N-1)p^4 (p-1)!^2 \epsilon^{j_{p-1} l_{M-p}}_{i_{p-1} k_{M-p}} \bar{\epsilon}^{i_{p-1} k_{M-p-1}}_{j_{p-1} l_{M-p}} \\
= \;& N(N-1)p^4 (p-1)!^2 (M-1)! \frac{(N-2)!}{(N-M-1)!} \\
= \;& \frac{N!(M-1)!p!^2}{(N-M)!}[p^2(N-M)]
\end{aligned}$$

where indices i, j have been deleted and contraction is done in effective $U(N-2)$ gauge theory.

- (4) Adding (2) and (3) together we have

  $$\epsilon^{j_p j}_{l_p i}\bar{\epsilon}^{k_p i}_{i_p j}\epsilon^{l_p l_{M-p}}_{k_p k_{M-p}}\bar{\epsilon}^{i_p k_{M-p}}_{j_p l_{M-p}} = \frac{N!(M-1)!p!^2}{(N-M)!}[(M-p)^2 + M(N-M) + p^2(N-M)]$$

  Putting factor $(N-p-1)!^2$ back we finally have

  $$\begin{aligned}\mathcal{E}_{II} &= \frac{N!(N-p-1)!^2 p!^2 M!}{(N-M-1)!}\left[1 + \frac{(M-p)^2}{M(N-M)} + \frac{p^2}{M}\right] \\ &= \frac{N!(M-1)!p!^2(N-p-1)!^2}{(N-M)!}[(M-p)^2 + M(N-M) + p^2(N-M)]\end{aligned}$$

To calculate the complete one-loop correction we need to insert four interaction terms. For each term, there are in principal 4! = 24 possible index contractions where each one could be as (pr more) complicated as (than) $\mathcal{E}_{II}$. From this we see that an explicit calculation of the one-loop correction is rather complicated. Thus our results provide a non-trivial check of our proposal concerning emergent gauge symmetry from D-brane operators in Yang-Mills theory.
